This is my own bulletin board

**This book is probably outdated already.** (Unless it was just downloaded from https://beginners.re/.)

The book is changing too often, content being added, bugs are (hopefully) being fixed. The latest version is always at https://beginners.re/.

This PDF you currently reading was compiled at July 5, 2019.

My dear readers! From time to time, I have questions, I don’t know who (or where) to ask. Or I’m just lazy... Can you please help me?

How to install and run Cyc?

Midnight Commander: I want to add a menu item (F2) like “cd path/DD/MM/YYYY”. What to do? Had no luck with cd ... $(date +%m) ...

How do you install VMware Remote Console 10.0.4 on Ubuntu 19? It just suddenly exits during installation. Is it known symptom?

Or what do you use to run VMware Workstation VMs on remote Ubuntu box?

What do you use on Linux in place of Adobe Acrobat Pro? To edit contents, add bookmarks, notes, highlight text...

What does tilde means in versions number in .dsc files, which describing Ubuntu packages? Some kind of wildcard? And what does >> means? Pipe is just OR? For example:

```
Build-Depends: cython-dbgl | python-pyrexl, ca-certificates, debhelper (>> 8.1.0-), python (>= 2.6.6-3), python-all-dev (== 2.6.6-3), python-all-dbgl (== 2.6.6-3), python-configobj (>= 4.7.2+ds-2), python-docutils, python-paramiko, python-pycurl-dbgl, python-subunit, python-testtools (>= 0.9.5-)
```

What do you use on unrooted Android device as a SSH server, that can write to external micro-SD card? I was happy with SSHDroid, but now it’s outdated... For instance, when Total Commander writes to micro-SD, a dialog box appears, whether to allow this or not. You allow it, and it can write to any folder on flash. This is not a case with SSH-servers that I saw.

A win32 process A is running. Process B is attaching to it as a debugger, or opens it using OpenProcess(). ReadProcessMemory() works OK, but fails if it tries to read uncommited memory pages of process A.

The problem: how to force the Windows Memory Manager to commit a page in process A from userland of process B? I can inject a read instruction into process A, run it, and the page would be committed, but this is not the solution.

If you know something, please help me: dennis@yurichev.com

Text version (July 5, 2019).

The latest version (and Russian edition) of this text is accessible at beginners.re.

The cover was made by Andy Nechaevsky: facebook.

Call for translators!

You may want to help me with translating this work into languages other than English and Russian. Just send me any piece of translated text (no matter how short) and I’ll put it into my LaTeX source code. Read here.

We already have something in German, French, a bit in Italian, Portuguese and Polish.

Speed isn’t important, because this is an open-source project, after all. Your name will be mentioned as a project contributor. Korean, Chinese, and Persian languages are reserved by publishers. English and Russian versions I do by myself, but my English is still that horrible, so I’m very grateful for any notes about grammar, etc. Even my Russian is flawed, so I’m grateful for notes about Russian text as well!

So do not hesitate to contact me: dennis@yurichev.com.

Preface

What is with two titles?

The book was named “Reverse Engineering for Beginners” in 2014-2018, but I always suspected this makes readership too narrow.

Infosec people know about “reverse engineering”, but I’ve rarely hear the “assembler” word from them. Likewise, the “reverse engineering” term is somewhat cryptic to a general audience of programmers, but they know about “assembler”.

In July 2018, as an experiment, I’ve changed the title to “Assembly Language for Beginners” and posted the link to Hacker News website\(^7\), and the book was received generally well.

So let it be, the book now has two titles.

However, I’ve changed the second title to “Understanding Assembly Language”, because someone had already written “Assembly Language for Beginners” book. Also, people say “for Beginners” sounds a bit sarcastic for a book of ~1000 pages.

The two books differ only by title, filename (UAL-XX.pdf versus RE4B-XX.pdf), URL and a couple of the first pages.

About reverse engineering

There are several popular meanings of the term “reverse engineering”:

1) The reverse engineering of software; researching compiled programs
2) The scanning of 3D structures and the subsequent digital manipulation required in order to duplicate them
3) Recreating DBMS\(^8\) structure

This book is about the first meaning.

Prerequisites

Basic knowledge of the C \(^9\) PL. Recommended reading: 12.1.3 on page 985.

Exercises and tasks

...can be found at: http://challenges.re.

About the author

Dennis Yurichev is an experienced reverse engineer and programmer. He can be contacted by email: dennis@yurichev.com.

Praise for this book

• “Now that Dennis Yurichev has made this book free (libre), it is a contribution to the world of free knowledge and free education.” Richard M. Stallman, GNU founder, software freedom activist.

• “It’s very well done .. and for free .. amazing.” Daniel Bilar, Siege Technologies, LLC.

• “... excellent and free” Pete Finnigan, Oracle RDBMS security guru.

• “... my compliments for the very nice tutorial!” Herbert Bos, full professor at the Vrije Universiteit Amsterdam, co-author of Modern Operating Systems (4th Edition).

• “... It is amazing and unbelievable.” Luis Rocha, CISSP / ISSAP, Technical Manager, Network & Information Security at Verizon Business.

• “Thanks for the great work and your book.” Joris van de Vis, SAP Netweaver & Security specialist.

• “... [a] reasonable intro to some of the techniques.” Mike Stay, teacher at the Federal Law Enforcement Training Center, Georgia, US.

• “I love this book! I have several students reading it at the moment, [and] plan to use it in graduate course.” Sergey Bratus, Research Assistant Professor at the Computer Science Department at Dartmouth College

• “Dennis @Yurichev has published an impressive (and free!) book on reverse engineering” Tanel Poder, Oracle RDBMS performance tuning expert.

• “This book is a kind of Wikipedia to beginners...” Archer, Chinese Translator, IT Security Researcher.

• “[A] first-class reference for people wanting to learn reverse engineering. And it’s free for all.” Mikko Hyppônén, F-Secure.

Thanks

For patiently answering all my questions: Slava “Avid” Kazakov, SkullC0DEr.

For helping me in other ways: Andrew Zubinski, Arnaud Patard (rtp on #debian-arm IRC), noshadow on #gcc IRC, Aliaksandr Autayeu, Mohsen Mostafa Jokar, Peter Sovietov, Misha “tiphareth” Verbitsky.

For translating the book into Simplified Chinese: Antiy Labs (antiy.cn), Archer.

For translating the book into Korean: Byungho Min.

For translating the book into Dutch: Cedric Sambre (AKA Mida).

For translating the book into Spanish: Diego Boy, Luis Alberto Espinosa Calvo, Fernando Guida, Diogo Mussi, Patricio Galdames.

For translating the book into Portuguese: Thales Stevan de A. Gois, Diogo Mussi, Luiz Filipe.

For translating the book into French: Florent Besnard, Marc Remy, Baudouin Landais, Téo Dacquet, BlueSkeye@GitHub.

For translating the book into German: Dennis Siekmeier, Julius Angres, Dirk Loser, Clemens Tamme.

For translating the book into Polish: Kateryna Rozanova, Aleksander Mistewicz, Wiktoria Lewicka.

For translating the book into Japanese: shmz@github.

Vasil Kolev did a great amount of work in proofreading and correcting many mistakes.

For illustrations and cover art: Andy Nechaevsky.

Thanks also to all the folks on github.com who have contributed notes and corrections.

Many \LaTeX packages were used: I would like to thank the authors as well.

Donors

Those who supported me during the time when I wrote significant part of the book:

mini-FAQ

Q: What are the prerequisites for reading this book?
A: A basic understanding of C/C++ is desirable.

Q: Should I really learn x86/x64/ARM and MIPS at once? Isn’t it too much?
A: Starters can read about just x86/x64, while skipping or skimming the ARM and MIPS parts.

Q: Can I buy a Russian or English hard copy/paper book?
A: Unfortunately, no. No publisher got interested in publishing a Russian or English version so far. Meanwhile, you can ask your favorite copy shop to print and bind it.

Q: Is there an epub or mobi version?
A: No. The book is highly dependent on TeX/LaTeX-specific hacks, so converting to HTML (epub/mobi are a set of HTMLs) would not be easy.

Q: Why should one learn assembly language these days?
A: Unless you are an OS developer, you probably don’t need to code in assembly—the latest compilers (2010s) are much better at performing optimizations than humans.

Also, the latest CPU’s are very complex devices, and assembly knowledge doesn’t really help towards understand their internals.

That being said, there are at least two areas where a good understanding of assembly can be helpful: First and foremost, for security/malware research. It is also a good way to gain a better understanding of your compiled code while debugging. This book is therefore intended for those who want to understand assembly language rather than to code in it, which is why there are many examples of compiler output contained within.

Q: I clicked on a hyperlink inside a PDF-document, how do I go back?

Q: May I print this book / use it for teaching?
A: Of course! That’s why the book is licensed under the Creative Commons license (CC BY-SA 4.0).

Q: Why is this book free? You’ve done great job. This is suspicious, as with many other free things.
A: In my own experience, authors of technical literature write mostly for self-advertisement purposes. It’s not possible to make any decent money from such work.

Q: How does one get a job in reverse engineering?
A: There are hiring threads that appear from time to time on reddit, devoted to RE (2016). Try looking there.

A somewhat related hiring thread can be found in the “netsec” subreddit: 2016.

Q: How can I learn programming in general?

31Operating System
32A very good text on this topic: [Agner Fog, The microarchitecture of Intel, AMD and VIA CPUs, (2016)]
33Central Processing Unit
34reddit.com/r/ReverseEngineering/

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!

Q: I have a question...

A: Send it to me by email (dennis@yurichev.com).

**How to learn programming**

Many people keep asking about it.

There is no “royal road”, but there are quite efficient ways.

From my own experience, this is just: solving exercises from:

- Harold Abelson, Gerald Jay Sussman, Julie Sussman – *Structure and Interpretation of Computer Programs*
- Donald E. Knuth, *The Art of Computer Programming*
- Niklaus Wirth’s books

... in pure C and LISP. You may never use these programming languages in future at all. Almost all commercial programmers don’t. But C and LISP coding experience will help enormously in long run. Also, you can skip reading books themselves, just skim them whenever you feel you need to understand something you missing for the exercise you currently solving.

This may take years at best, or a lifetime, but still this is way faster than to rush between fads.

The success of these books probably related to the fact that their authors are teachers and all this material has been honed on students first.

As of LISP, I personally would recommend Racket (Scheme dialect). But this is matter of taste, anyway.

Some people say assembly language understanding is also very helpful, even if you will never use it. This is true. But this is a way for the most dedicated geeks, and it can be postponed at start.

Also, self-taught people (including author of these lines) often has the problem of trying too hard on hard problems, skipping easy ones. This is a great mistake. Compare to sport or music – no one starts at 100kg weights, or Paganini’s Caprices. I would say – you can try to tackle a problem if you can outline its solution in your mind.

---

I think the art of doing research consists largely of asking questions, and sometimes answering them. Learn how to repeatedly pose miniquestions that represent special cases of the big questions you are hoping to solve.

When you begin to explore some area, you take baby steps at first, building intuition about that territory. Play with many small examples, trying to get a complete understanding of particular parts of the general situation.

In that way you learn many properties that are true and many properties that are false. That gives guidance about directions that are fruitful versus directions to avoid.

Eventually your brain will have learned how to take larger and larger steps. And shazam, you’ll be ready to take some giant steps and solve the big problem.

But don’t stop there! At this point you’ll be one of very few people in the world who have ever understood your problem area so well. It will therefore be your responsibility to discover what else is true, in the neighborhood of that problem, using the same or similar methods to what your brain can now envision. Take your results to their “natural boundary” (in a sense analogous to the natural boundary where a function of a complex variable ceases to be analytic).

My little book *Surreal Numbers* provides an authentic example of research as it is happening. The characters in that story make false starts and useful discoveries in exactly the same order as I myself made those false starts and useful discoveries, when I first studied

---

35 *Structure and Interpretation of Computer Programs*
John Conway's fascinating axioms about number systems — his amazingly simple axioms that go significantly beyond real-valued numbers.

(One of the characters in that book tends to succeed or fail by brute force and patience; the other is more introspective, and able to see a bigger picture. Both of them represent aspects of my own activities while doing research. With that book I hoped to teach research skills “by osmosis”, as readers observe a detailed case study.)

Surreal Numbers deals with a purely mathematical topic, not especially close to computer science; it features algebra and logic, not algorithms. When algorithms become part of the research, a beautiful new dimension also comes into play: Algorithms can be implemented on computers!

I strongly recommend that you look for every opportunity to write programs that carry out all or a part of whatever algorithms relate to your research. In my experience the very act of writing such a program never fails to deepen my understanding of the problem area.

( Donald E. Knuth - https://theorydish.blog/2018/02/01/donald-knuth-on-doing-research/ )

Good luck!

About the Korean translation

In January 2015, the Acorn publishing company (www.acornpub.co.kr) in South Korea did a huge amount of work in translating and publishing this book (as it was in August 2014) into Korean.

It’s available now at their website.

The translator is Byungho Min (twitter/tais9). The cover art was done by the artistic Andy Nechaevsky, a friend of the author: facebook/andydinka. Acorn also holds the copyright to the Korean translation.

So, if you want to have a real book on your shelf in Korean and want to support this work, it is now available for purchase.

About the Persian/Farsi translation

In 2016 the book was translated by Mohsen Mostafa Jokar (who is also known to Iranian community for his translation of Radare manual[36]). It is available on the publisher's website[37] (Pendare Pars).

Here is a link to a 40-page excerpt: https://beginners.re/farsi.pdf.

About the Chinese translation

In April 2017, translation to Chinese was completed by Chinese PTPress. They are also the Chinese translation copyright holders.

The principal translator is Archer, to whom the author owes very much. He was extremely meticulous (in a good sense) and reported most of the known mistakes and bugs, which is very important in literature such as this book. The author would recommend his services to any other author!

The guys from Antiy Labs has also helped with translation. Here is preface written by them.

Chapter 1

Code Patterns

1.1 The method

When the author of this book first started learning C and, later, C++, he used to write small pieces of code, compile them, and then look at the assembly language output. This made it very easy for him to understand what was going on in the code that he had written. 1 He did this so many times that the relationship between the C/C++ code and what the compiler produced was imprinted deeply in his mind. It’s now easy for him to imagine instantly a rough outline of a C code’s appearance and function. Perhaps this technique could be helpful for others.

By the way, there is a great website where you can do the same, with various compilers, instead of installing them on your box. You can use it as well: https://godbolt.org/.

Exercises

When the author of this book studied assembly language, he also often compiled small C functions and then rewrote them gradually to assembly, trying to make their code as short as possible. This probably is not worth doing in real-world scenarios today, because it’s hard to compete with the latest compilers in terms of efficiency. It is, however, a very good way to gain a better understanding of assembly. Feel free, therefore, to take any assembly code from this book and try to make it shorter. However, don’t forget to test what you have written.

Optimization levels and debug information

Source code can be compiled by different compilers with various optimization levels. A typical compiler has about three such levels, where level zero means that optimization is completely disabled. Optimization can also be targeted towards code size or code speed. A non-optimizing compiler is faster and produces more understandable (albeit verbose) code, whereas an optimizing compiler is slower and tries to produce code that runs faster (but is not necessarily more compact). In addition to optimization levels, a compiler can include some debug information in the resulting file, producing code that is easy to debug. One of the important features of the ‘debug’ code is that it might contain links between each line of the source code and its respective machine code address. Optimizing compilers, on the other hand, tend to produce output where entire lines of source code can be optimized away and thus not even be present in the resulting machine code. Reverse engineers can encounter either version, simply because some developers turn on the compiler’s optimization flags and others do not. Because of this, we’ll try to work on examples of both debug and release versions of the code featured in this book, wherever possible.

Sometimes some pretty ancient compilers are used in this book, in order to get the shortest (or simplest) possible code snippet.

---

1In fact, he still does this when he can’t understand what a particular bit of code does.
1.2 Some basics

1.2.1 A short introduction to the CPU

The CPU is the device that executes the machine code a program consists of.

A short glossary:

**Instruction**: A primitive CPU command. The simplest examples include: moving data between registers, working with memory, primitive arithmetic operations. As a rule, each CPU has its own instruction set architecture (ISA).

**Machine code**: Code that the CPU directly processes. Each instruction is usually encoded by several bytes.

**Assembly language**: Mnemonic code and some extensions, like macros, that are intended to make a programmer’s life easier.

**CPU register**: Each CPU has a fixed set of general purpose registers (GPR), ≈ 8 in x86, ≈ 16 in x86-64, and also ≈ 16 in ARM. The easiest way to understand a register is to think of it as an untyped temporary variable. Imagine if you were working with a high-level PL and could only use eight 32-bit (or 64-bit) variables. Yet a lot can be done using just these!

One might wonder why there needs to be a difference between machine code and a PL. The answer lies in the fact that humans and CPUs are not alike—it is much easier for humans to use a high-level PL like C/C++, Java, or Python, but it is easier for a CPU to use a much lower level of abstraction. Perhaps it would be possible to invent a CPU that can execute high-level PL code, but it would be many times more complex than the CPUs we know of today. In a similar fashion, it is very inconvenient for humans to write in assembly language, due to it being so low-level and difficult to write in without making a huge number of annoying mistakes. The program that converts the high-level PL code into assembly is called a compiler.

A couple of words about different ISAs

The x86 ISA has always had variable-length instructions, so when the 64-bit era came, the x64 extensions did not impact the ISA very significantly. In fact, the x86 ISA still contains a lot of instructions that first appeared in 16-bit 8086 CPU, yet are still found in the CPUs of today. ARM is a RISC CPU designed with constant-length instructions in mind, which had some advantages in the past. In the very beginning, all ARM instructions were encoded in 4 bytes. This is now referred to as “ARM mode”. Then they realized it wasn’t as frugal as they first imagined. In fact, the most common CPU instructions in real world applications can be encoded using less information. They therefore added another ISA, called Thumb, in which each instruction was encoded in just 2 bytes. This is now referred to as “Thumb mode”. However, not all ARM instructions can be encoded in just 2 bytes, so the Thumb instruction set is somewhat limited. It is worth noting that code compiled for ARM mode and Thumb mode can coexist within one single program. The ARM creators thought Thumb could be extended, giving rise to Thumb-2, which appeared in ARMv7. Thumb-2 still uses 2-byte instructions, but has some new instructions which have the size of 4 bytes. There is a common misconception that Thumb-2 is a mix of ARM and Thumb. This is incorrect. Rather, Thumb-2 was extended to fully support all processor features so it could compete with ARM mode—a goal that was clearly achieved, as the majority of applications for iPod/iPhone/iPad are compiled for the Thumb-2 instruction set. (Though, admittedly, this is largely due to the fact that Xcode does this by default). Later the 64-bit ARM came out. This ISA has 4-byte instructions, and lacked the need of any additional Thumb mode. However, the 64-bit requirements affected the ISA, resulting in us now having three ARM instruction sets: ARM mode, Thumb mode (including Thumb-2) and ARM64. These ISAs intersect partially, but it can be said that they are different ISAs, rather than variations of the same one. Therefore, we will try to add fragments of code in all three ARM ISAs in this book. There are, by the way, many other RISC ISAs with fixed length 32-bit instructions, such as MIPS, PowerPC and Alpha AXP.

---

2 General Purpose Registers
3 Old-school Russian literature also uses the term “translator”.
4 Reduced Instruction Set Computing
5 Fixed-length instructions are handy because one can calculate the next (or previous) instruction address without effort. This feature will be discussed in the switch() operator (1.21.2 on page 175) section.
6 e.g. MOV/PUSH/CALL/jcc

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
1.2.2 Numeral Systems

Nowadays octal numbers seem to be used for exactly one purpose—file permissions on POSIX systems—but hexadecimal numbers are widely used to emphasize the bit pattern of a number over its numeric value.

Alan A. A. Donovan, Brian W. Kernighan — The Go Programming Language

Humans have become accustomed to a decimal numeral system, probably because almost everyone has 10 fingers. Nevertheless, the number “10” has no significant meaning in science and mathematics. The natural numeral system in digital electronics is binary: 0 is for an absence of current in the wire, and 1 for presence. 10 in binary is 2 in decimal, 100 in binary is 4 in decimal, and so on.

If the numeral system has 10 digits, it has a radix (or base) of 10. The binary numeral system has a radix of 2.

Important things to recall:
1) A number is a number, while a digit is a term from writing systems, and is usually one character
2) The value of a number does not change when converted to another radix; only the writing notation for that value has changed (and therefore the way of representing it in RAM).

1.2.3 Converting From One Radix To Another

Positional notation is used almost every numerical system. This means that a digit has weight relative to where it is placed inside of the larger number. If 2 is placed at the rightmost place, it’s 2, but if it’s placed one digit before rightmost, it’s 20.

What does 1234 stand for?

10^3 \cdot 1 + 10^2 \cdot 2 + 10^1 \cdot 3 + 1 \cdot 4 = 1234 
or 1000 \cdot 1 + 100 \cdot 2 + 10 \cdot 3 + 4 = 1234

It’s the same story for binary numbers, but the base is 2 instead of 10. What does 0b101011 stand for?

d_3 \cdot 2^3 + d_2 \cdot 2^2 + d_1 \cdot 2^1 + d_0 \cdot 2^0 = 43 
or d_5 \cdot 2^5 + d_4 \cdot 2^4 + d_3 \cdot 2^3 + d_2 \cdot 2^2 + d_1 \cdot 2^1 + d_0 \cdot 2^0 = 43

There is such a thing as non-positional notation, such as the Roman numeral system. Perhaps, humankind switched to positional notation because it’s easier to do basic operations (addition, multiplication, etc.) on paper by hand.

Binary numbers can be added, subtracted and so on in the very same as taught in schools, but only 2 digits are available.

Binary numbers are bulky when represented in source code and dumps, so that is where the hexadecimal numeral system can be useful. A hexadecimal radix uses the digits 0..9, and also 6 Latin characters: A..F. Each hexadecimal digit takes 4 bits or 4 binary digits, so it’s very easy to convert from binary number to hexadecimal and back, even manually, in one’s mind.

7Random-Access Memory

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
How can one tell which radix is being used in a specific instance?

Decimal numbers are usually written as is, i.e., 1234. Some assemblers allow an identifier on decimal radix numbers, in which the number would be written with a “d” suffix: 1234d.

Binary numbers are sometimes prepended with the “0b” prefix: 0b100110111 (GCC\(^9\) has a non-standard language extension for this\(^10\)). There is also another way: using a “b” suffix, for example: 100110111b. This book tries to use the “0b” prefix consistently throughout the book for binary numbers.

Hexadecimal numbers are prepended with “0x” prefix in C/C++ and other PLs: 0x1234ABCD. Alternatively, they are given a “h” suffix: 1234ABCDh. This is common way of representing them in assemblers and debuggers. In this convention, if the number is started with a Latin (A..F) digit, a 0 is added at the beginning: 0ABCDEFh. There was also convention that was popular in 8-bit home computers era, using $ prefix, like $ABCD. The book will try to stick to “0x” prefix throughout the book for hexadecimal numbers.

Should one learn to convert numbers mentally? A table of 1-digit hexadecimal numbers can easily be memorized. As for larger numbers, it’s probably not worth tormenting yourself.

Perhaps the most visible hexadecimal numbers are in URL\(^11\)s. This is the way that non-Latin characters are encoded. For example: https://en.wiktionary.org/wiki/na%C3%AFvet%C3%A9 is the URL of Wiktionary article about “naïveté” word.

### Octal Radix

Another numeral system heavily used in the past of computer programming is octal. In octal there are 8 digits (0..7), and each is mapped to 3 bits, so it’s easy to convert numbers back and forth. It has been superseded by the hexadecimal system almost everywhere, but, surprisingly, there is a *NIX utility, used often by many people, which takes octal numbers as argument: chmod.

As many *NIX users know, chmod argument can be a number of 3 digits. The first digit represents the rights of the owner of the file (read, write and/or execute), the second is the rights for the group to which the file belongs, and the third is for everyone else. Each digit that chmod takes can be represented in binary form:

<table>
<thead>
<tr>
<th>decimal</th>
<th>binary</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>111</td>
<td>rwx</td>
</tr>
<tr>
<td>6</td>
<td>110</td>
<td>rw-</td>
</tr>
<tr>
<td>5</td>
<td>101</td>
<td>r-x</td>
</tr>
<tr>
<td>4</td>
<td>100</td>
<td>r--</td>
</tr>
<tr>
<td>3</td>
<td>011</td>
<td>-wx</td>
</tr>
<tr>
<td>2</td>
<td>010</td>
<td>-w-</td>
</tr>
<tr>
<td>1</td>
<td>001</td>
<td>--x</td>
</tr>
<tr>
<td>0</td>
<td>000</td>
<td>---</td>
</tr>
</tbody>
</table>

So each bit is mapped to a flag: read/write/execute.

The importance of chmod here is that the whole number in argument can be represented as octal number. Let’s take, for example, 644. When you run chmod 644 file, you set read/write permissions for owner, read permissions for group and again, read permissions for everyone else. If we convert the octal number 644 to binary, it would be 110110000, or, in groups of 3 bits, 110 100 100.

Now we see that each triplet describe permissions for owner/group/others: first is rw-, second is r-- and third is r--.

The octal numeral system was also popular on old computers like PDP-8, because word there could be 12, 24 or 36 bits, and these numbers are all divisible by 3, so the octal system was natural in that environment.

---

\(^9\)GNU Compiler Collection  
\(^10\)https://gcc.gnu.org/onlinedocs/gcc/Binary-constants.html  
\(^11\)Uniform Resource Locator

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Nowadays, all popular computers employ word/address sizes of 16, 32 or 64 bits, and these numbers are all divisible by 4, so the hexadecimal system is more natural there.

The octal numeral system is supported by all standard C/C++ compilers. This is a source of confusion sometimes, because octal numbers are encoded with a zero prepended, for example, 0377 is 255. Sometimes, you might make a typo and write “09” instead of 9, and the compiler would report an error. GCC might report something like this:
error: invalid digit "9" in octal constant.

Also, the octal system is somewhat popular in Java. When the IDA shows Java strings with non-printable characters, they are encoded in the octal system instead of hexadecimal. The JAD Java decompiler behaves the same way.

**Divisibility**

When you see a decimal number like 120, you can quickly deduce that it’s divisible by 10, because the last digit is zero. In the same way, 123400 is divisible by 100, because the two last digits are zeros.

Likewise, the hexadecimal number \(0x1230\) is divisible by \(0x10\) (or 16), \(0x123000\) is divisible by \(0x1000\) (or 4096), etc.

The binary number \(0b1000101000\) is divisible by \(0b1000\) (8), etc.

This property can often be used to quickly realize if an address or a size of some block in memory is padded to some boundary. For example, sections in **Portable Executable** files are almost always started at addresses ending with 3 hexadecimal zeros: \(0x41000\), \(0x10001000\), etc. The reason behind this is the fact that almost all PE sections are padded to a boundary of \(0x1000\) (4096) bytes.

**Multi-Precision Arithmetic and Radix**

Multi-precision arithmetic can use huge numbers, and each one may be stored in several bytes. For example, RSA keys, both public and private, span up to 4096 bits, and maybe even more.

In [Donald E. Knuth, *The Art of Computer Programming*, Volume 2, 3rd ed., (1997), 265] we find the following idea: when you store a multi-precision number in several bytes, the whole number can be represented as having a radix of \(2^8 = 256\), and each digit goes to the corresponding byte. Likewise, if you store a multi-precision number in several 32-bit integer values, each digit goes to each 32-bit slot, and you may think about this number as stored in radix of \(2^{32}\).

**How to Pronounce Non-Decimal Numbers**

Numbers in a non-decimal base are usually pronounced by digit by digit: “one-zero-zero-one-one-...”. Words like “ten” and “thousand” are usually not pronounced, to prevent confusion with the decimal base system.

**Floating point numbers**

To distinguish floating point numbers from integers, they are usually written with “.0” at the end, like 0.0, 123.0, etc.

### 1.3 An Empty Function

The simplest possible function is arguably one that does nothing:

```c/c++
void f()
{
    return;
};
```

\(^{12}\text{Portable Executable}\)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let’s compile it!

1.3.1 x86

Here’s what both the GCC and MSVC compilers produce on the x86 platform:

Listing 1.2: Optimizing GCC/MSVC (assembly output)

```
f:  
    ret  
```

There is just one instruction: RET, which returns execution to the caller.

1.3.2 ARM

Listing 1.3: Optimizing Keil 6/2013 (ARM mode) assembly output

```
f PROC  
    BX lr  
ENDP  
```

The return address is not saved on the local stack in the ARM ISA, but rather in the link register, so the BX LR instruction causes execution to jump to that address—effectively returning execution to the caller.

1.3.3 MIPS

There are two naming conventions used in the world of MIPS when naming registers: by number (from $0 to $31) or by pseudo name ($V0, $A0, etc.).

The GCC assembly output below lists registers by number:

Listing 1.4: Optimizing GCC 4.4.5 (assembly output)

```
j  $31  
nop  
```

...while IDA\(^{13}\) does it by pseudo name:

Listing 1.5: Optimizing GCC 4.4.5 (IDA)

```
j  $ra  
nop  
```

The first instruction is the jump instruction (J or JR) which returns the execution flow to the caller, jumping to the address in the $31 (or $RA) register.

This is the register analogous to LR\(^{14}\) in ARM.

The second instruction is NOP\(^{15}\), which does nothing. We can ignore it for now.

A Note About MIPS Instructions and Register Names

Register and instruction names in the world of MIPS are traditionally written in lowercase. However, for the sake of consistency, this book will stick to using uppercase letters, as it is the convention followed by all the other ISAs featured in this book.

\(^{13}\) Interactive Disassembler and Debugger developed by Hex-Rays
\(^{14}\) Link Register
\(^{15}\) No Operation

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
1.3.4 Empty Functions in Practice

Despite the fact empty functions seem useless, they are quite frequent in low-level code. First of all, they are quite popular in debugging functions, like this one:

Listing 1.6: C/C++ code

```c
void dbg_print (const char *fmt, ...) {
    #ifdef _DEBUG
        // open log file
        // write to log file
        // close log file
    #endif
}
void some_function() {
    ...
    dbg_print("we did something\n");
    ...
};
```

In a non-debug build (as in a “release”), _DEBUG is not defined, so the dbg_print() function, despite still being called during execution, will be empty.

Similarly, a popular method of software protection is to make one build for legal customers, and another demo build. A demo build can lack some important functions, as with this example:

Listing 1.7: C/C++ code

```c
void save_file () {
    #ifndef DEMO
        // a real saving code
    #endif
};
```

The save_file() function can be called when the user clicks File->Save on the menu. The demo version may be delivered with this menu item disabled, but even if a software cracker will enable it, only an empty function with no useful code will be called.

IDA marks such functions with names like nullsub_00, nullsub_01, etc.

1.4 Returning Values

Another simple function is the one that simply returns a constant value:

Listing 1.8: C/C++ Code

```c
int f() {
    return 123;
};
```

Let’s compile it.

1.4.1 x86

Here’s what both the GCC and MSVC compilers produce (with optimization) on the x86 platform:

Listing 1.9: Optimizing GCC/MSVC (assembly output)

```
f:            
    mov eax, 123
    ret
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There are just two instructions: the first places the value 123 into the EAX register, which is used by convention for storing the return value, and the second one is RET, which returns execution to the caller. The caller will take the result from the EAX register.

### 1.4.2 ARM

There are a few differences on the ARM platform:

```assembly
PROC
MOV r0, #0x7b; 123
BX lr
ENDP
```

ARM uses the register R0 for returning the results of functions, so 123 is copied into R0.

It is worth noting that MOV is a misleading name for the instruction in both the x86 and ARM ISAs. The data is not in fact moved, but copied.

### 1.4.3 MIPS

The GCC assembly output below lists registers by number:

```assembly
j $31
li $2, 123 # 0x7b
```

...while IDA does it by their pseudo names:

```assembly
jr $ra
li $v0, 0x7B
```

The $2 (or $V0) register is used to store the function’s return value. LI stands for “Load Immediate” and is the MIPS equivalent to MOV.

The other instruction is the jump instruction (J or JR) which returns the execution flow to the caller.

You might be wondering why the positions of the load instruction (LI) and the jump instruction (J or JR) are swapped. This is due to a RISC feature called “branch delay slot”.

The reason this happens is a quirk in the architecture of some RISC ISAs and isn’t important for our purposes—we must simply keep in mind that in MIPS, the instruction following a jump or branch instruction is executed before the jump/branch instruction itself.

As a consequence, branch instructions always swap places with the instruction executed immediately beforehand.

In practice, functions which merely return 1 (true) or 0 (false) are very frequent.

The smallest ever of the standard UNIX utilities, /bin/true and /bin/false return 0 and 1 respectively, as an exit code. (Zero as an exit code usually means success, non-zero means error.)

### 1.5 Hello, world!

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
#include <stdio.h>

int main()
{
    printf("hello, world\n");
    return 0;
}

## 1.5.1 x86

### MSVC

Let's compile it in MSVC 2010:

```bash
cl 1.cpp /Fa1.asm
```

(The /Fa option instructs the compiler to generate an assembly listing file)

### Listings

#### Listing 1.13: C/C++ Code

```c
#include <stdio.h>

int main()
{
    printf("hello, world\n");
    return 0;
}
```

#### Listing 1.14: MSVC 2010

```assembly
CONST SEGMENT
$SG3830 DB 'hello, world', 0AH, 00H
CONST ENDS
PUBLIC _main
EXTRN _printf:PROC
; Function compile flags: /Odtp
_TEXT SEGMENT
_main PROC
    push ebp
    mov ebp, esp
    push OFFSET $SG3830
    call _printf
    add esp, 4
    xor eax, eax
    pop ebp
    ret 0
_main ENDP
_TEXT ENDS
```

MSVC produces assembly listings in Intel-syntax. The differences between Intel-syntax and AT&T-syntax will be discussed in 1.5.1 on page 11.

The compiler generated the file, 1.obj, which is to be linked into 1.exe. In our case, the file contains two segments: CONST (for data constants) and _TEXT (for code).

The string `hello, world` in C/C++ has type `const char[]`[Bjarne Stroustrup, *The C++ Programming Language, 4th Edition*, (2013)p176, 7.3.2], but it does not have its own name. The compiler needs to deal with the string somehow, so it defines the internal name `$SG3830` for it.

That is why the example may be rewritten as follows:

```c
#include <stdio.h>

const char $SG3830[]="hello, world\n";

int main()
{
    printf($SG3830);
    return 0;
}
```

Let's go back to the assembly listing. As we can see, the string is terminated by a zero byte, which is standard for C/C++ strings. More about C/C++ strings: 5.4.1 on page 703.

In the code segment, _TEXT, there is only one function so far: main(). The function main() starts with prologue code and ends with epilogue code (like almost any function)\(^\text{16}\).

\(^\text{16}\)You can read more about it in the section about function prologues and epilogues (1.6 on page 28).

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
After the function prologue we see the call to the printf() function:

CALL _printf. Before the call, a string address (or a pointer to it) containing our greeting is placed on the stack with the help of the PUSH instruction.

When the printf() function returns the control to the main() function, the string address (or a pointer to it) is still on the stack. Since we do not need it anymore, the stack pointer (the ESP register) needs to be corrected.

ADD ESP, 4 means add 4 to the ESP register value.

Why 4? Since this is a 32-bit program, we need exactly 4 bytes for address passing through the stack. If it was x64 code we would need 8 bytes. ADD ESP, 4 is effectively equivalent to POP register but without using any register.

For the same purpose, some compilers (like the Intel C++ Compiler) may emit POP ECX instead of ADD (e.g., such a pattern can be observed in the Oracle RDBMS code as it is compiled with the Intel C++ compiler). This instruction has almost the same effect but the ECX register contents will be overwritten. The Intel C++ compiler supposedly uses POP ECX since this instruction's opcode is shorter than ADD ESP, x (1 byte for POP against 3 for ADD).

Here is an example of using POP instead of ADD from Oracle RDBMS:

```
.text:0000029A push ebx
.text:0000029B call qksfroChild
.text:000002A0 pop ecx
```

After calling printf(), the original C/C++ code contains the statement return 0 —return 0 as the result of the main() function.

In the generated code this is implemented by the instruction XOR EAX, EAX.

XOR is in fact just "eXclusive OR" but the compilers often use it instead of MOV EAX, 0—again because it is a slightly shorter opcode (2 bytes for XOR against 5 for MOV).

Some compilers emit SUB EAX, EAX, which means SUBtract the value in the EAX from the value in EAX. That in any case will results in zero.

The last instruction RET returns the control to the caller. Usually, this is C/C++ CRT code which in turn returns control to the OS.

**GCC**

Now let’s try to compile the same C/C++ code in the GCC 4.4.1 compiler in Linux: gcc 1.c -o 1. Next, with the assistance of the IDA disassembler, let’s see how the main() function was created. IDA, like MSVC, uses Intel-syntax.

```
Listing 1.16: code in IDA

main proc near
var_10 = dword ptr -10h
  push ebp
  mov ebp, esp
  and esp, 0FFFFFFF0h
  sub esp, 10h
  mov eax, offset aHelloWorld ; "hello, world\n"
  mov [esp+10h+var_10], eax
  call _printf
  mov eax, 0
  leave
  ret
main endp
```

17CPU flags, however, are modified
18Wikipedia
19C Runtime library
20We could also have GCC produce assembly listings in Intel-syntax by applying the options -S -masm=intel.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The result is almost the same. The address of the hello, world string (stored in the data segment) is loaded in the EAX register first, and then saved onto the stack. In addition, the function prologue has AND ESP, 0xFFFFFF0h —this instruction aligns the ESP register value on a 16-byte boundary. This results in all values in the stack being aligned the same way (The CPU performs better if the values it is dealing with are located in memory at addresses aligned on a 4-byte or 16-byte boundary).

SUB ESP, 10h allocates 16 bytes on the stack. Although, as we can see hereafter, only 4 are necessary here.

This is because the size of the allocated stack is also aligned on a 16-byte boundary.

The string address (or a pointer to the string) is then stored directly onto the stack without using the PUSH instruction. var_10 —is a local variable and is also an argument for printf(). Read about it below.

Then the printf() function is called.

Unlike MSVC, when GCC is compiling without optimization turned on, it emits MOV EAX, 0 instead of a shorter opcode.

The last instruction, LEAVE —is the equivalent of the MOV ESP, EBP and POP EBP instruction pair—in other words, this instruction sets the stack pointer (ESP) back and restores the EBP register to its initial state. This is necessary since we modified these register values (ESP and EBP) at the beginning of the function (by executing MOV EBP, ESP / AND ESP, …).

### GCC: AT&T syntax

Let’s see how this can be represented in assembly language AT&T syntax. This syntax is much more popular in the UNIX-world.

**Listing 1.17: let’s compile in GCC 4.7.3**

```
gcc -S 1_1.c
```

We get this:

**Listing 1.18: GCC 4.7.3**

```
.LC0:
.string "hello, world\n"
.text
.globl main
.type main, @function
main:
.LFB0:
.cfi_startproc
pushl %ebp
.cfi_def_cfa_offset 8
.cfi_offset 5, -8
movl %esp, %ebp
.cfi_def_cfa_register 5
andl $-16, %esp
subl $16, %esp
movl $.LC0, (%esp)
call printf
movl $0, %eax
leave
.cfi_restore 5
.cfi_def_cfa 4, 4
ret
.cfi_endproc
.LFE0:
.size main, .-main
.ident "GCC: (Ubuntu/Linaro 4.7.3-1ubuntu1) 4.7.3"
.section .note.GNU-stack, "", @progbits
```

Wikipedia: Data structure alignment

(For statistics collecting purposes) if you’ve read this far, please click [here]. Thanks!
The listing contains many macros (the parts that begin with a dot). These are not interesting for us at the moment.

For now, for the sake of simplicity, we can ignore them (except the `.string` macro which encodes a null-terminated character sequence just like a C-string). Then we’ll see this:

```
Listing 1.19: GCC 4.7.3

.LC0:
   .string "hello, world\n"
main:
   pushl %ebp
   movl %esp, %ebp
   andl $-16, %esp
   subl $16, %esp
   movl $.LC0, (%esp)
   call printf
   movl $0, %eax
   leave
   ret
```

Some of the major differences between Intel and AT&T syntax are:

- Source and destination operands are written in opposite order.
  - In Intel-syntax: `<instruction> <destination operand> <source operand>`.  
  - In AT&T syntax: `<instruction> <source operand> <destination operand>`.  

  Here is an easy way to memorize the difference: when you deal with Intel-syntax, you can imagine that there is an equality sign (=) between operands and when you deal with AT&T-syntax imagine there is a right arrow (→).

- AT&T: Before register names, a percent sign must be written (%) and before numbers a dollar sign ($). Parentheses are used instead of brackets.
- AT&T: A suffix is added to instructions to define the operand size:
  - q — quad (64 bits)
  - l — long (32 bits)
  - w — word (16 bits)
  - b — byte (8 bits)

To go back to the compiled result: it is almost identical to what was displayed by IDA. There is one subtle difference: `0xFFFFFFFF0` is presented as `-16`. It’s the same thing: 16 in the decimal system is `0x10` in hexadecimal. -`0x10` is equal to `0xFFFFFFFF0` (for a 32-bit data type).

One more thing: the return value is set to 0 by using the usual MOV, not XOR. MOV just loads a value to a register. Its name is a misnomer (as the data is not moved but rather copied). In other architectures, this instruction is named “LOAD” or “STORE” or something similar.

### String patching (Win32)

We can easily find the “hello, world” string in the executable file using Hiew:

---

22This GCC option can be used to eliminate “unnecessary” macros: `-fno-asynchronous-unwind-tables`

23By the way, in some C standard functions (e.g., `memcpy()`, `strcpy()`) the arguments are listed in the same way as in Intel-syntax: first the pointer to the destination memory block, and then the pointer to the source memory block.
And we can try to translate our message into Spanish:

**Figure 1.2: Hiew**

The Spanish text is one byte shorter than English, so we also added the 0x0A byte at the end (\n) with a zero byte.

It works.

What if we want to insert a longer message? There are some zero bytes after original English text. It’s hard to say if they can be overwritten: they may be used somewhere in CRT code, or maybe not. Anyway, only overwrite them if you really know what you’re doing.

**String patching (Linux x64)**

Let’s try to patch a Linux x64 executable using rada.re:

```bash
Listing 1.20: rada.re session
dennis@bigbox ~/tmp % gcc hw.c
dennis@bigbox ~/tmp % radare2 a.out
-- SHALL WE PLAY A GAME?
[0x00400430]> / hello
Searching 5 bytes from 0x00080000 to 0x00601040: 68 65 6c 6c 6f
Searching 5 bytes in [0x400000-0x601040] hits: 1
0x004005c4 hit0_0 .HHhello, world;0.
[0x004005c4]> s 0x004005c4
0x004005c4 6865 6c6c 6f2c 2077 6f72 6c64 0000 0000 hello, world....
0x004005d4 011b 033b 3000 0000 0500 0000 1cfe ffff ...;0.......... 
0x004005e4 7c00 0000 5cfe ffff 4c00 0000 52ff ffff |\.|\.|...R...
0x004005f4 a400 0000 6cff ffff 0400 0000 0f3f ffff ....l...........
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Here's what's going on: I searched for the “hello” string using the / command, then I set the cursor (seek, in rada.re terms) to that address. Then I want to be sure that this is really that place: px dumps bytes there. oo+ switches rada.re to read-write mode. w writes an ASCII string at the current seek. Note the \00 at the end—this is a zero byte. q quits.

This is a real story of software cracking

An image processing software, when not registered, added watermarks, like “This image was processed by evaluation version of [software name]”, across a picture. We tried at random: we found that string in the executable file and put spaces instead of it. Watermarks disappeared. Technically speaking, they continued to appear. With the help of Qt functions, the watermark was still added to the resulting image. But adding spaces didn’t alter the image itself...

Software localization of MS-DOS era

This method was a common way to translate MS-DOS software to Russian language back to 1980’s and 1990’s. Russian words and sentences are usually slightly longer than its English counterparts, so that is why localized software has a lot of weird acronyms and hardly readable abbreviations.

![Localized Norton Commander 5.51](image)

Perhaps this also happened to other languages during that era, in other countries.
In x86-64, all registers were extended to 64-bit, and now their names have an R- prefix. In order to use the stack less often (in other words, to access external memory/cache less often), there is a popular way to pass function arguments via registers (fastcall) 6.1.3 on page 734. I.e., a part of the function’s arguments are passed in registers, and the rest—via the stack. In Win64, 4 function arguments are passed in the RCX, RDX, R8, and R9 registers. That is what we see here: a pointer to the string for printf() is now passed not in the stack, but rather in the RCX register. The pointers are 64-bit now, so they are passed in the 64-bit registers (which have the R- prefix). However, for backward compatibility, it is still possible to access the 32-bit parts, using the E- prefix. This is how the RAX/EAX/AX/AL register looks like in x86-64:

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAX&lt;sup&gt;x64&lt;/sup&gt;</td>
<td>EAX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>AX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>AH</td>
<td>AL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The main() function returns an int-typed value, which in C/C++ is still 32-bit, for better backward compatibility and portability, so that is why the EAX register is cleared at the function end (i.e., the 32-bit part of the register) instead of with RAX. There are also 40 bytes allocated in the local stack. This is called the “shadow space”, which we’ll talk about later: 1.14.2 on page 100.

**GCC: x86-64**

Let’s also try GCC in 64-bit Linux:

```c
Listing 1.22: GCC 4.4.6 x64

.string "hello, world\n"
main:
    sub    rsp, 8
    mov    edi, OFFSET FLAT:.LC0 ; "hello, world\n"
    xor    eax, eax ; number of vector registers passed
    call   printf
    xor    eax, eax
    add    rsp, 8
    ret

```

Linux, *BSD and Mac OS X also use a method to pass function arguments in registers. [Michael Matz, Jan Hubicka, Andreas Jaeger, Mark Mitchell, *System V Application Binary Interface. AMD64 Architecture Processor Supplement*, (2013)]

The first 6 arguments are passed in the RDI, RSI, RDX, RCX, R8, and R9 registers, and the rest—via the stack.

So the pointer to the string is passed in EDI (the 32-bit part of the register). Why doesn’t it use the 64-bit part, RDI?

It is important to keep in mind that all MOV instructions in 64-bit mode that write something into the lower 32-bit register part also clear the higher 32-bits (as stated in Intel manuals: 12.1.4 on page 986). I.e., the MOV EAX, 01122344h writes a value into RAX correctly, since the higher bits will be cleared.

If we open the compiled object file (.o), we can also see all the instructions’ opcodes:

```c
Listing 1.23: GCC 4.4.6 x64

.text:00000000004004D0  main   proc near
.text:00000000004004D0  48 83 EC 08   sub    rsp, 8
```

<sup>24</sup>Also available as [https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf](https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf)

<sup>25</sup>This must be enabled in Options → Disassembly → Number of opcode bytes

(For statistics collecting purposes) if you’ve read this far, please click [here](https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf). Thanks!
As we can see, the instruction that writes into EDI at 0x4004D4 occupies 5 bytes. The same instruction writing a 64-bit value into RDI occupies 7 bytes. Apparently, GCC is trying to save some space. Besides, it can be sure that the data segment containing the string will not be allocated at the addresses higher than 4GiB.

We also see that the EAX register has been cleared before the printf() function call. This is done because according to ABI\textsuperscript{26} standard mentioned above, the number of used vector registers is to be passed in EAX in *NIX systems on x86-64.

**Address patching (Win64)**

If our example was compiled in MSVC 2013 using /MD switch (meaning a smaller executable due to MSVCR*.DLL file linkage), the main() function comes first, and can be easily found:

![Figure 1.4: Hiew](image)

As an experiment, we can increment address by 1:

\textsuperscript{26}Application Binary Interface
Hiew shows “ello, world”. And when we run the patched executable, this very string is printed.

Pick another string from binary image (Linux x64)

The binary file I’ve got when I compile our example using GCC 5.4.0 on Linux x64 box has many other text strings. They are mostly imported function names and library names.

Run objdump to get the contents of all sections of the compiled file:

```
$ objdump -s a.out

a.out: file format elf64-x86-64

Contents of section .interp:
400238 2f6c6962 36342f6c 642d6c69 6e75782d /lib64/ld-linux-x86-64.so.2.
400248 7383362d 36342e73 6f2e3200 x86-64.so.2.

Contents of section .note.ABI-tag:
400254 04000000 10000000 01000000 474e5500 ............GNU.
400264 00000000 02000000 06000000 20000000 .............

Contents of section .note.gnu.build-id:
400274 04000000 14000000 03000000 474e5500 ............GNU.
400284 fe461178 5bb710b4 bbf2aca8 5ec1ec10 .F.x[.......^...
400294 cf3f7ae4 .?z.

...
int main()
{
    printf(0x400238);
    return 0;
}

It’s hard to believe, but this code prints the aforementioned string.

If you would change the address to 0x400260, the “GNU” string would be printed. This address is true for my specific GCC version, GNU toolset, etc. On your system, the executable may be slightly different, and all addresses will also be different. Also, adding/removing code to/from this source code will probably shift all addresses back or forward.

1.5.3 ARM

For my experiments with ARM processors, several compilers were used:

- Apple Xcode 4.6.3 IDE with the LLVM-GCC 4.2 compiler.
- GCC 4.9 (Linaro) (for ARM64), available as win32-executables at http://go.yurichev.com/17325.

32-bit ARM code is used (including Thumb and Thumb-2 modes) in all cases in this book, if not mentioned otherwise. When we talk about 64-bit ARM here, we call it ARM64.

Non-optimizing Keil 6/2013 (ARM mode)

Let’s start by compiling our example in Keil:

armcc.exe --arm --c90 -O0 1.c

The armcc compiler produces assembly listings in Intel-syntax, but it has high-level ARM-processor related macros, but it is more important for us to see the instructions “as is” so let’s see the compiled result in IDA.

Listing 1.24: Non-optimizing Keil 6/2013 (ARM mode) IDA

```
.text:00000000       main
.text:00000000       10 40 2D E9       STMFD  SP!, {R4,LR}
.text:00000004       1E 0E 8F E2       ADR    R0, aHelloWorld ; "hello, world"
.text:00000008       15 19 00 EB       BL     __2printf
.text:0000000C       00 00 A0 E3       MOV    R0, #0
.text:00000010       10 80 BD EB       LDMFD  SP!, {R4,PC}
.text:000001EC       68 65 6C 6C+aHelloWorld DCB "hello, world",0 ; DATA XREF: main+4
```

In the example, we can easily see each instruction has a size of 4 bytes. Indeed, we compiled our code for ARM mode, not for Thumb.

The very first instruction, STMFD SP!, {R4,LR} works as an x86 PUSH instruction, writing the values of two registers (R4 and LR) into the stack.

Indeed, in the output listing from the armcc compiler, for the sake of simplification, actually shows the PUSH {r4,lr} instruction. But that is not quite precise. The PUSH instruction is only available in Thumb mode. So, to make things less confusing, we’re doing this in IDA.

This instruction first decrements the SP so it points to the place in the stack that is free for new entries, then it saves the values of the R4 and LR registers at the address stored in the modified SP.

This instruction (like the PUSH instruction in Thumb mode) is able to save several register values at once which can be very useful. By the way, this has no equivalent in x86. It can also be noted that the STMFD instruction is a generalization of the PUSH instruction (extending its features), since it can work with any

27It is indeed so: Apple Xcode 4.6.3 uses open-source GCC as front-end compiler and LLVM code generator
28e.g. ARM mode lacks PUSH/POP instructions
29STMFD
30stack pointer. SP/ESP/RSP in x86/x64. SP in ARM.
register, not just with SP. In other words, STMFD may be used for storing a set of registers at the specified memory address.

The ADR R0, aHelloWorld instruction adds or subtracts the value in the PC\textsuperscript{32} register to the offset where the hello, world string is located. How is the PC register used here, one might ask? This is called “position-independent code”\textsuperscript{33}.

Such code can be executed at a non-fixed address in memory. In other words, this is PC-relative addressing. The ADR instruction takes into account the difference between the address of this instruction and the address where the string is located. This difference (offset) is always to be the same, no matter at what address our code is loaded by the OS. That’s why all we need is to add the address of the current instruction (from PC) in order to get the absolute memory address of our C-string.

BL __2printf\textsuperscript{34} instruction calls the printf() function. Here’s how this instruction works:

- store the address following the BL instruction (0xC) into the LR;
- then pass the control to printf() by writing its address into the PC register.

When printf() finishes its execution it must have information about where it needs to return the control to. That’s why each function passes control to the address stored in the LR register.

That is a difference between “pure” RISC-processors like ARM and CISC\textsuperscript{35}-processors like x86, where the return address is usually stored on the stack. Read more about this in next section (6.4.1 on page 747).

By the way, an absolute 32-bit address or offset cannot be encoded in the 32-bit BL instruction because it only has space for 24 bits. As we may recall, all ARM-mode instructions have a size of 4 bytes (32 bits). Hence, they can only be located on 4-byte boundary addresses. This implies that the last 2 bits of the instruction address (which are always zero bits) may be omitted. In summary, we have 26 bits for offset encoding. This is enough to encode \( \text{current}_{PC} \pm 32M \).

Next, the MOV R0, #0\textsuperscript{36} instruction just writes 0 into the R0 register. That’s because our C-function returns 0 and the return value is to be placed in the R0 register.

The last instruction LDMFD SP!, R4,PC\textsuperscript{37}. It loads values from the stack (or any other memory place) in order to save them into R4 and PC, and increments the stack pointer SP. It works like POP here. N.B. The very first instruction STMFD saved the R4 and LR registers pair on the stack, but R4 and PC are restored during the LDMFD execution.

As we already know, the address of the place where each function must return control to is usually saved in the LR register. The very first instruction saves its value in the stack because the same register will be used by our main() function when calling printf(). In the function’s end, this value can be written directly to the PC register, thus passing control to where our function has been called.

Since main() is usually the primary function in C/C++, the control will be returned to the OS loader or to a point in a CRT, or something like that.

All that allows omitting the BX LR instruction at the end of the function.

DCB is an assembly language directive defining an array of bytes or ASCII strings, akin to the DB directive in the x86-assembly language.

Non-optimizing Keil 6/2013 (Thumb mode)

Let’s compile the same example using Keil in Thumb mode:

```
armcc.exe --thumb --c90 -O0 1.c
```

We are getting (in IDA):

```plaintext
Listing 1.25: Non-optimizing Keil 6/2013 (Thumb mode) + IDA

.text:00000000  main
.text:00000000  10 B5  PUSH  {R4,LR}
.text:00000002  C8 A0  ADR  R0, aHelloWorld ; "hello, world"
.text:00000004  06 F0 2E F9  BL  __2printf
```

\textsuperscript{33}Program Counter. IP/EIP/RIP in x86/64. PC in ARM.

\textsuperscript{38}LDMFD\textsuperscript{39} is an inverse instruction of STMFD

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We can easily spot the 2-byte (16-bit) opcodes. This is, as was already noted, Thumb. The BL instruction, however, consists of two 16-bit instructions. This is because it is impossible to load an offset for the `printf()` function while using the small space in one 16-bit opcode. Therefore, the first 16-bit instruction loads the higher 10 bits of the offset and the second instruction loads the lower 11 bits of the offset.

As was noted, all instructions in Thumb mode have a size of 2 bytes (or 16 bits). This implies it is impossible for a Thumb-instruction to be at an odd address whatsoever. Given the above, the last address bit may be omitted while encoding instructions.

In summary, the BL Thumb-instruction can encode an address in $current\_PC \pm \approx 2^M$.

As for the other instructions in the function: PUSH and POP work here just like the described STMFD/LDMFD only the SP register is not mentioned explicitly here. ADR works just like in the previous example. MOV writes 0 into the R0 register in order to return zero.

### Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Xcode 4.6.3 without optimization turned on produces a lot of redundant code so we’ll study optimized output, where the instruction count is as small as possible, setting the compiler switch -O3.

```assembly
#text:000028C4  hello_world
#text:000028C4 80 40 2D E9  STMFD   SP!, {R7,LR}
#text:000028C8 86 06 01 E3  MOV     R0, #0x1686
#text:000028CC 0D 7A 00 E1  MOV     R7, SP
#text:000028D0 00 00 40 E3  MOVT    R0, #0
#text:000028D4 00 00 8F E0  ADD     R0, PC, R0
#text:000028D8 C3 05 00 EB  BL      _puts
#text:000028DC 00 00 A0 E3  MOV     R0, #0
#text:000028E0 80 80 BD E8  LDMFD  SP!, {R7,PC}
```

The instructions STMFD and LDMFD are already familiar to us.

The MOV instruction just writes the number 0x1686 into the R0 register. This is the offset pointing to the “Hello world!” string.

The R7 register (as it is standardized in [iOS ABI Function Call Guide, (2010)](http://go.yurichev.com/17276)) is a frame pointer. More on that below.

The MOVT R0, #0 (MOVve Top) instruction writes 0 into higher 16 bits of the register. The issue here is that the generic MOV instruction in ARM mode may write only the lower 16 bits of the register.

Keep in mind, all instruction opcodes in ARM mode are limited in size to 32 bits. Of course, this limitation is not related to moving data between registers. That’s why an additional instruction MOVT exists for writing into the higher bits (from 16 to 31 inclusive). Its usage here, however, is redundant because the MOV R0, #0x1686 instruction above cleared the higher part of the register. This is supposedly a shortcoming of the compiler.

The ADD R0, PC, R0 instruction adds the value in the PC to the value in the R0, to calculate the absolute address of the “Hello world!” string. As we already know, it is “position-independent code” so this correction is essential here.

The BL instruction calls the puts() function instead of printf().

GCC replaced the first printf() call with puts(). Indeed: printf() with a sole argument is almost analogous to puts().

Almost, because the two functions are producing the same result only in case the string does not contain printf format identifiers starting with %. In case it does, the effect of these two functions would be different.

39 Also available as [http://go.yurichev.com/17276](http://go.yurichev.com/17276)

40 It has also to be noted the puts() does not require a “n” new line symbol at the end of a string, so we do not see it here.
Why did the compiler replace the `printf()` with `puts()`? Presumably because `puts()` is faster. Because it just passes characters to `stdout` without comparing every one of them with the `%` symbol.

Next, we see the familiar `MOV R0, #0` instruction intended to set the R0 register to 0.

**Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)**

By default Xcode 4.6.3 generates code for Thumb-2 in this manner:

```
__text:00002BC   hello_world
__text:00002BC+80 B5        PUSH      {R7,LR}
__text:000026E 41 F2 D8 30   MOVW      R0, #0x1308
__text:0000272 6F 46        MOV       R7, SP
__text:0000274 C0 F2 00 00   MOV.T    R0, #0
__text:0000278 78 44        ADD       R0, PC
__text:000027A 01 F0 38 EA   BLX      puts
__text:000027E 08 20        MOVS     R0, #0
__text:0000280 80 B0        POP       {R7,PC}
...
__cstring:00003E70 48 65 6C 6F 20+aHelloWorld DCB "Hello world!",0xA,0
```

The BL and BLX instructions in Thumb mode, as we recall, are encoded as a pair of 16-bit instructions. In Thumb-2 these *surrogate* opcodes are extended in such a way so that new instructions may be encoded here as 32-bit instructions.

That is obvious considering that the opcodes of the Thumb-2 instructions always begin with 0xFx or 0xEx.

But in the IDA listing the opcode bytes are swapped because for ARM processor the instructions are encoded as follows: last byte comes first and after that comes the first one (for Thumb and Thumb-2 modes) or for instructions in ARM mode the fourth byte comes first, then the third, then the second and finally the first (due to different *endianness*).

So that is how bytes are located in IDA listings:
- for ARM and ARM64 modes: 4-3-2-1;
- for Thumb mode: 2-1;
- for 16-bit instructions pair in Thumb-2 mode: 2-1-4-3.

So as we can see, the `MOVW`, `MOVT.W` and BLX instructions begin with 0xFx.

One of the Thumb-2 instructions is `MOVW` R0, #0x1308 —it stores a 16-bit value into the lower part of the R0 register, clearing the higher bits.

Also, `MOVT.W` R0, #0 works just like `MOVT` from the previous example only it works in Thumb-2.

Among the other differences, the BLX instruction is used in this case instead of the BL.

The difference is that, besides saving the RA\(^42\) in the LR register and passing control to the `puts()` function, the processor is also switching from Thumb/Thumb-2 mode to ARM mode (or back).

This instruction is placed here since the instruction to which control is passed looks like (it is encoded in ARM mode):

```
__symbolstub1:00003FEC  puts ; CODE XREF: hello_world+8
__symbolstub1:00003FEC 44 F0 9F E5   LDR   PC, =__imp__puts
```

This is essentially a jump to the place where the address of `puts()` is written in the imports’ section.

So, the observant reader may ask: why not call `puts()` right at the point in the code where it is needed? Because it is not very space-efficient.

Almost any program uses external dynamic libraries (like DLL in Windows, .so in *NIX or .dylib in Mac OS X). The dynamic libraries contain frequently used library functions, including the standard C-function `puts()`.

\(^{41}\)ciselant.de/projects/gcc_printf/gcc_printf.html
\(^{42}\)Return Address

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
In an executable binary file (Windows PE .exe, ELF or Mach-O) an import section is present. This is a list of symbols (functions or global variables) imported from external modules along with the names of the modules themselves.

The OS loader loads all modules it needs and, while enumerating import symbols in the primary module, determines the correct addresses of each symbol.

In our case, __imp__puts is a 32-bit variable used by the OS loader to store the correct address of the function in an external library. Then the LDR instruction just reads the 32-bit value from this variable and writes it into the PC register, passing control to it.

So, in order to reduce the time the OS loader needs for completing this procedure, it is good idea to write the address of each symbol only once, to a dedicated place.

Besides, as we have already figured out, it is impossible to load a 32-bit value into a register while using only one instruction without a memory access.

Therefore, the optimal solution is to allocate a separate function working in ARM mode with the sole goal of passing control to the dynamic library and then to jump to this short one-instruction function (the so-called thunk function) from the Thumb-code.

By the way, in the previous example (compiled for ARM mode) the control is passed by the BL to the same thunk function. The processor mode, however, is not being switched (hence the absence of an “X” in the instruction mnemonic).

More about thunk-functions

Thunk-functions are hard to understand, apparently, because of a misnomer. The simplest way to understand it as adaptors or convertors of one type of jack to another. For example, an adaptor allowing the insertion of a British power plug into an American wall socket, or vice-versa. Thunk functions are also sometimes called wrappers.

Here are a couple more descriptions of these functions:

"A piece of coding which provides an address:“, according to P. Z. Ingerman, who invented thunks in 1961 as a way of binding actual parameters to their formal definitions in Algol-60 procedure calls. If a procedure is called with an expression in the place of a formal parameter, the compiler generates a thunk which computes the expression and leaves the address of the result in some standard location.

...Microsoft and IBM have both defined, in their Intel-based systems, a “16-bit environment” (with bletcherous segment registers and 64K address limits) and a “32-bit environment” (with flat addressing and semi-real memory management). The two environments can both be running on the same computer and OS (thanks to what is called, in the Microsoft world, WOW which stands for Windows On Windows). MS and IBM have both decided that the process of getting from 16- to 32-bit and vice versa is called a “thunk”; for Windows 95, there is even a tool, THUNK.EXE, called a “thunk compiler”.

( The Jargon File )

Another example we can find in LAPACK library—a “Linear Algebra PACKage” written in FORTRAN. C/C++ developers also want to use LAPACK, but it's insane to rewrite it to C/C++ and then maintain several versions. So there are short C functions callable from C/C++ environment, which are, in turn, call FORTRAN functions, and do almost anything else:

```c
double Blas_Dot_Prod(const LaVectorDouble &dx, const LaVectorDouble &dy)
{
    assert(dx.size()==dy.size());
    integer n = dx.size();
    integer incx = dx.inc(), incy = dy.inc();
    return F77NAME(ddot)(&n, &dx(0), &incx, &dy(0), &incy);
}
```

Also, functions like that are called “wrappers”.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's compile the example using GCC 4.8.1 in ARM64:

```
<table>
<thead>
<tr>
<th>00000000000400590 &lt;main&gt;:</th>
</tr>
</thead>
<tbody>
<tr>
<td>4000590: a9bf7bfd stp x29, x30, [sp,#-16]!</td>
</tr>
<tr>
<td>4000594: 910003 mov x29, sp</td>
</tr>
<tr>
<td>4000598: 90000000 adrp x0, 400000 &lt;_init-0x3b8&gt;</td>
</tr>
<tr>
<td>400059c: 91192000 add x0, x0, #0x648</td>
</tr>
<tr>
<td>40005a0: 97ffffa0 bl 400420 <a href="mailto:puts@plt">puts@plt</a></td>
</tr>
<tr>
<td>40005a4: 52800000 mov w0, #0 // #0</td>
</tr>
<tr>
<td>40005a8: a8c17bfd ldp x29, x30, [sp],#16</td>
</tr>
<tr>
<td>40005ac: d65f03c0 ret</td>
</tr>
</tbody>
</table>
```

Contents of section .rodata:
- `400640 01000200 00000000 48656c6c 6f210a00 .........Hello!`

There are no Thumb and Thumb-2 modes in ARM64, only ARM, so there are 32-bit instructions only. The register count is doubled: .2.4 on page 1014. 64-bit registers have X- prefixes, while its 32-bit parts—W-.

The STP instruction (Store Pair) saves two registers in the stack simultaneously: X29 and X30.

Of course, this instruction is able to save this pair at an arbitrary place in memory, but the SP register is specified here, so the pair is saved in the stack.

ARM64 registers are 64-bit ones, each has a size of 8 bytes, so one needs 16 bytes for saving two registers.

The STP instruction saves two registers in the stack simultaneously: X29 and X30.

ARM64 registers are 64-bit ones, each has a size of 8 bytes, so one needs 16 bytes for saving two registers.

The exclamation mark ("!" ) after the operand means that 16 is to be subtracted from SP first, and only then are values from register pair to be written into the stack. This is also called pre-index. About the difference between post-index and pre-index read here: 1.39.2 on page 444.

Hence, in terms of the more familiar x86, the first instruction is just an analogue to a pair of PUSH X29 and PUSH X30. X29 is used as FP in ARM64, and X30 as LR, so that’s why they are saved in the function prologue and restored in the function epilogue.

The second instruction copies SP in X29 (or FP). This is made so to set up the function stack frame.

ADRP and ADD instructions are used to fill the address of the string “Hello!” into the X0 register, because the first function argument is passed in this register. There are no instructions, whatsoever, in ARM that can store a large number into a register (because the instruction length is limited to 4 bytes, read more about it here: 1.39.3 on page 445). So several instructions must be utilized. The first instruction (ADRP) writes the address of the 4KiB page, where the string is located, into X0, and the second one (ADD) just adds the remainder to the address. More about that in: 1.39.4 on page 447.

0x400000 + 0x648 = 0x400648, and we see our “Hello!” C-string in the .rodata data segment at this address.

puts() is called afterwards using the BL instruction. This was already discussed: 1.5.3 on page 20.

MOV writes 0 into W0. W0 is the lower 32 bits of the 64-bit X0 register:

```
<table>
<thead>
<tr>
<th>High 32-bit part</th>
<th>low 32-bit part</th>
</tr>
</thead>
<tbody>
<tr>
<td>X0</td>
<td>W0</td>
</tr>
</tbody>
</table>
```

The function result is returned via X0 and main() returns 0, so that’s how the return result is prepared. But why use the 32-bit part?

Because the int data type in ARM64, just like in x86-64, is still 32-bit, for better compatibility.

So if a function returns a 32-bit int, only the lower 32 bits of X0 register have to be filled.

In order to verify this, let’s change this example slightly and recompile it. Now main() returns a 64-bit value:

---

43Frame Pointer

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.29: main() returning a value of uint64_t type

```c
#include <stdio.h>
#include <stdint.h>

uint64_t main()
{
    printf("Hello!\n");
    return 0;
}
```

The result is the same, but that's how MOV at that line looks like now:

### Listing 1.30: Non-optimizing GCC 4.8.1 + objdump

```
4005a4:    d2800000 mov x0, #0x0 // #0
```

LDP (Load Pair) then restores the X29 and X30 registers.

There is no exclamation mark after the instruction: this implies that the values are first loaded from the stack, and only then is SP increased by 16. This is called post-index.

A new instruction appeared in ARM64: RET. It works just as BX LR, only a special hint bit is added, informing the CPU that this is a return from a function, not just another jump instruction, so it can execute it more optimally.

Due to the simplicity of the function, optimizing GCC generates the very same code.

### 1.5.4 MIPS

#### A word about the “global pointer”

One important MIPS concept is the “global pointer”. As we may already know, each MIPS instruction has a size of 32 bits, so it’s impossible to embed a 32-bit address into one instruction: a pair has to be used for this (like GCC did in our example for the text string address loading). It’s possible, however, to load data from the address in the range of register−32768...register+32767 using one single instruction (because 16 bits of signed offset could be encoded in a single instruction). So we can allocate some register for this purpose and also allocate a 64KiB area of most used data. This allocated register is called a “global pointer” and it points to the middle of the 64KiB area. This area usually contains global variables and addresses of imported functions like printf(), because the GCC developers decided that getting the address of some function must be as fast as a single instruction execution instead of two. In an ELF file this 64KiB area is located partly in sections .sbss (“small BSS”) for uninitialized data and .sdata (“small data”) for initialized data. This implies that the programmer may choose what data he/she wants to be accessed fast and place it into .sdata/.sbss. Some old-school programmers may recall the MS-DOS memory model 11.6 on page 976 or the MS-DOS memory managers like XMS/EMS where all memory was divided in 64KiB blocks.

This concept is not unique to MIPS. At least PowerPC uses this technique as well.

#### Optimizing GCC

Let’s consider the following example, which illustrates the “global pointer” concept.

### Listing 1.31: Optimizing GCC 4.4.5 (assembly output)

```
$LC0:
; \000 is zero byte in octal base:
.ascii "Hello, world!\012\000"
main:
; function prologue.
; set the GP:
    lui $28,%hi(__gnu_local_gp)
    addiu $sp,$sp,-32
    addiu $28,$28,%lo(__gnu_local_gp)
; save the RA to the local stack:
    sw $31,28($sp)
```

44 Block Started by Symbol

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As we see, the $GP register is set in the function prologue to point to the middle of this area. The RA register is also saved in the local stack. puts() is also used here instead of printf(). The address of the puts() function is loaded into $25 using LW the instruction ("Load Word"). Then the address of the text string is loaded to $4 using LUI ("Load Upper Immediate") and ADDIU ("Add Immediate Unsigned Word") instruction pair. LUI sets the high 16 bits of the register (hence "upper" word in instruction name) and ADDIU adds the lower 16 bits of the address.

ADDIU follows JALR (haven’t you forgot branch delay slots yet?). The register $4 is also called $A0, which is used for passing the first function argument.

JALR ("Jump and Link Register") jumps to the address stored in the $25 register (address of puts()) while saving the address of the next instruction (LW) in RA. This is very similar to ARM. Oh, and one important thing is that the address saved in RA is not the address of the next instruction (because it’s in a delay slot and is executed before the jump instruction), but the address of the instruction after the next one (after the delay slot). Hence, PC+8 is written to RA during the execution of JALR, in our case, this is the address of the LW instruction next to ADDIU.

LW ("Load Word") at line 20 restores RA from the local stack (this instruction is actually part of the function epilogue).

MOVE at line 22 copies the value from the $0 ($ZERO) register to $2 ($V0).

MIPS has a constant register, which always holds zero. Apparently, the MIPS developers came up with the idea that zero is in fact the busiest constant in the computer programming, so let’s just use the $0 register every time zero is needed.

Another interesting fact is that MIPS lacks an instruction that transfers data between registers. In fact, MOVE DST, SRC is ADD DST, SRC, $ZERO ($DST = SRC + 0), which does the same. Apparently, the MIPS developers wanted to have a compact opcode table. This does not mean an actual addition happens at each MOVE instruction. Most likely, the CPU optimizes these pseudo instructions and the ALU46 is never used.

J at line 24 jumps to the address in RA, which is effectively performing a return from the function. ADDIU after J is in fact executed before J (remember branch delay slots?) and is part of the function epilogue. Here is also a listing generated by IDA. Each register here has its own pseudo name:

Listings 1.32: Optimizing GCC 4.4.5 (IDA)

45The MIPS registers table is available in appendix 3.1 on page 1015

46Arithmetic Logic Unit
The instruction at line 15 saves the GP value into the local stack, and this instruction is missing mysteriously from the GCC output listing, maybe by a GCC error\footnote{47}. The GP value has to be saved indeed, because each function can use its own 64KiB data window. The register containing the \texttt{puts()} address is called $T9$, because registers prefixed with T- are called “temporaries” and their contents may not be preserved.

### Non-optimizing GCC

Non-optimizing GCC is more verbose.

Listing 1.33: Non-optimizing GCC 4.4.5 (assembly output)

```
reglo:
  .ascii "Hello, world\!\012\000"
main:
 ; function prologue.
 ; save the RA ($31) and FP in the stack:
  addiu $sp,$sp,-32
  sw $31,28($sp)
  sw $fp,24($sp)
 ; set the FP (stack frame pointer):
  move $fp,$sp
 ; set the GP:
  lui $28,%hi($reglo)
  addiu $28,$28,%lo($reglo)
 ; load the address of the text string:
  lui $2,%hi($reglo)
  addiu $4,$2,%lo($reglo)
 ; load the address of \texttt{puts()} using the GP:
  lw $2,%call16(puts)($28)
  nop
 ; call \texttt{puts()}:
  move $25,$2
  jalr $25
  nop ; branch delay slot
 ; restore the GP from the local stack:
  lw $28,16($fp)
 ; set register $2 ($V0) to zero:
  move $2,$0
 ; function epilogue.
 ; restore the SP:
  move $sp,$fp
 ; restore the RA:
  lw $31,28($sp)
 ; restore the FP:
  lw $fp,24($sp)
  addiu $sp,$sp,32
 ; jump to the RA:
  j $31
  nop ; branch delay slot
```

\footnote{47Apparently, functions generating listings are not so critical to GCC users, so some unfixed cosmetic bugs may still exist.}

(For statistics collecting purposes) if you’ve read this far, please click \texttt{here}. Thanks!
We see here that register FP is used as a pointer to the stack frame. We also see 3 NOPs. The second and third of which follow the branch instructions. Perhaps the GCC compiler always adds NOPs (because of branch delay slots) after branch instructions and then, if optimization is turned on, maybe eliminates them. So in this case they are left here.

Here is also IDA listing:

Listing 1.34: Non-optimizing GCC 4.4.5 (IDA)

```
.text:00000000 main:
.text:00000000
.text:00000000 var_10 = -0x10
.text:00000000 var_8 = -8
.text:00000000 var_4 = -4
.text:00000000
; function prologue.
.text:00000000 addiu $sp, -0x20
.text:00000004 sw $ra, 0x20+var_4($sp)
.text:00000008 sw $fp, 0x20+var_8($sp)
; set the FP (stack frame pointer):
.text:00000010 la $gp, __gnu_local_gp
.text:00000014 move $fp, $sp
; load the address of the text string:
.text:0000001C lui $v0, (aHelloWorld >> 16) # "Hello, world!"
.text:00000020 addiu $a0, $v0, (aHelloWorld & 0xFFFF) # "Hello, world!"
.text:00000024 lw $v0, (puts & 0xFFFF)($gp)
.text:00000028 or $at, $zero ; NOP
; call puts():
.text:0000002C move $t9, $v0
.text:00000030 jalr $t9
.text:00000034 or $at, $zero ; NOP
; restore the GP from local stack:
.text:00000038 lw $gp, 0x20+var_10($fp)
; set register $2 ($V0) to zero:
.text:0000003C move $v0, $zero
; function epilogue.
.text:00000040 move $sp, $fp
; restore the RA:
.text:00000044 lw $ra, 0x20+var_4($sp)
; restore the FP:
.text:00000048 lw $fp, 0x20+var_8($sp)
.text:0000004C addiu $sp, $0x20
; jump to the RA:
.text:00000050 jr $ra
.text:00000054 or $at, $zero ; NOP
```

Interestingly, IDA recognized the LUI/ADDIU instructions pair and coalesced them into one LA ("Load Address") pseudo instruction at line 15. We may also see that this pseudo instruction has a size of 8 bytes! This is a pseudo instruction (or macro) because it's not a real MIPS instruction, but rather a handy name for an instruction pair.

Another thing is that IDA doesn’t recognize NOP instructions, so here they are at lines 22, 26 and 41. It is OR $AT, $ZERO. Essentially, this instruction applies the OR operation to the contents of the $AT register with zero, which is, of course, an idle instruction. MIPS, like many other ISAs, doesn’t have a separate NOP instruction.

**Role of the stack frame in this example**

The address of the text string is passed in the register. Why setup a local stack anyway? The reason for this lies in the fact that the values of registers RA and GP have to be saved somewhere (because printf() is called), and the local stack is used for this purpose. If this was a leaf function, it would have been possible to get rid of the function prologue and epilogue, for example: 1.4.3 on page 8.
Optimizing GCC: load it into GDB

1.5.5 Conclusion

The main difference between x86/ARM and x64/ARM64 code is that the pointer to the string is now 64-bits in length. Indeed, modern CPUs are now 64-bit due to both the reduced cost of memory and the greater demand for it by modern applications. We can add much more memory to our computers than 32-bit pointers are able to address. As such, all pointers are now 64-bit.

1.5.6 Exercises

- http://challenges.re/48
- http://challenges.re/49

1.6 Function prologue and epilogue

A function prologue is a sequence of instructions at the start of a function. It often looks something like the following code fragment:

```
push ebp
mov ebp, esp
sub esp, X
```
What these instruction do: save the value of the EBP register on the stack, set the value of the EBP register to the value of the ESP and then allocate space on the stack for local variables.

The value in the EBP stays the same over the period of the function execution and is to be used for local variables and arguments access. For the same purpose one can use ESP, but since it changes over time this approach is not too convenient.

The function epilogue frees the allocated space in the stack, returns the value in the EBP register back to its initial state and returns the control flow to the caller:

```
mov esp, ebp
pop ebp
ret 0
```

Function prologues and epilogues are usually detected in disassemblers for function delimitation.

### 1.6.1 Recursion

Epilogues and prologues can negatively affect the recursion performance.

More about recursion in this book: [3.5.3 on page 488](#).

### 1.7 An Empty Function: redux

Let’s back to the empty function example [1.3 on page 5](#). Now that we know about function prologue and epilogue, this is an empty function [1.1 on page 5](#) compiled by non-optimizing GCC:

Listing 1.36: Non-optimizing GCC 8.2 x64 (assembly output)

```
f:
push rbp
mov rbp, rsp
nop
pop rbp
ret
```

It’s RET, but function prologue and epilogue, probably, wasn’t optimized and left as is. NOP is seems another compiler artefact. Anyway, the only effective instruction here is RET. All other instructions can be removed (or optimized).

### 1.8 Returning Values: redux

Again, when we know about function prologue and epilogue, let’s recompile an example returning a value ([ 1.4 on page 7](#), [1.8 on page 7](#)) using non-optimizing GCC:

Listing 1.37: Non-optimizing GCC 8.2 x64 (assembly output)

```
f:
push rbp
mov rbp, rsp
mov eax, 123
pop rbp
ret
```

Effective instructions here are MOV and RET, others are – prologue and epilogue.

### 1.9 Stack

The stack is one of the most fundamental data structures in computer science. AKA [LIFO](#). (For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!

---

48 [wikipedia.org/wiki/Call_stack](https://en.wikipedia.org/wiki/Call_stack)

49 Also Known As

50 Last In First Out
Technically, it is just a block of memory in process memory along with the ESP or RSP register in x86 or x64, or the SP register in ARM, as a pointer within that block.

The most frequently used stack access instructions are PUSH and POP (in both x86 and ARM Thumb-mode). PUSH subtracts from ESP/RSP/SP 4 in 32-bit mode (or 8 in 64-bit mode) and then writes the contents of its sole operand to the memory address pointed by ESP/RSP/SP.

POP is the reverse operation: retrieve the data from the memory location that SP points to, load it into the instruction operand (often a register) and then add 4 (or 8) to the stack pointer.

After stack allocation, the stack pointer points at the bottom of the stack. PUSH decreases the stack pointer and POP increases it. The bottom of the stack is actually at the beginning of the memory allocated for the stack block. It seems strange, but that’s the way it is.

ARM supports both descending and ascending stacks.

For example the STMFD/LDMFD, STMED/LDMED instructions are intended to deal with a descending stack (grows downwards, starting with a high address and progressing to a lower one). The STMFA/LDMFA, STMEA/LDMEA instructions are intended to deal with an ascending stack (grows upwards, starting from a low address and progressing to a higher one).

### 1.9.1 Why does the stack grow backwards?

Intuitively, we might think that the stack grows upwards, i.e. towards higher addresses, like any other data structure.

The reason that the stack grows backward is probably historical. When the computers were big and occupied a whole room, it was easy to divide memory into two parts, one for the heap and one for the stack. Of course, it was unknown how big the heap and the stack would be during program execution, so this solution was the simplest possible.

![Stack Diagram](#)

In [D. M. Ritchie and K. Thompson, *The UNIX Time Sharing System*, (1974)](http://go.yurichev.com/17270) we can read:

> The user-core part of an image is divided into three logical segments. The program text segment begins at location 0 in the virtual address space. During execution, this segment is write-protected and a single copy of it is shared among all processes executing the same program. At the first 8K byte boundary above the program text segment in the virtual address space begins a nonshared, writable data segment, the size of which may be extended by a system call. Starting at the highest address in the virtual address space is a stack segment, which automatically grows downward as the hardware’s stack pointer fluctuates.

This reminds us how some students write two lecture notes using only one notebook: notes for the first lecture are written as usual, and notes for the second one are written from the end of notebook, by flipping it. Notes may meet each other somewhere in between, in case of lack of free space.

1.9.2 What is the stack used for?

Save the function’s return address

x86

When calling another function with a CALL instruction, the address of the point exactly after the CALL instruction is saved to the stack and then an unconditional jump to the address in the CALL operand is executed.

The CALL instruction is equivalent to a PUSH address_after_call / JMP operand instruction pair.

RET fetches a value from the stack and jumps to it —that is equivalent to a POP tmp / JMP tmp instruction pair.

Overflowing the stack is straightforward. Just run eternal recursion:

```c
void f()
{
    f();
}
```

MSVC 2008 reports the problem:

```
c:\tmp6>cl ss.cpp /Fass.asm
Microsoft (R) 32-bit C/C++ Optimizing Compiler Version 15.00.21022.08 for 80x86
Copyright (C) Microsoft Corporation. All rights reserved.

ss.cpp
C:\tmp6\ss.cpp(4) : warning C4717: 'f' : recursive on all control paths, function will cause \ runtime stack overflow
```

...but generates the right code anyway:

```asm
?f@@YAXXZ PROC ; f
; Line 2
    push    ebp
    mov     ebp, esp
; Line 3
    call    ?f@@YAXXZ ; f
; Line 4
    pop      ebp
    ret
?f@@YAXXZ ENDP ; f
```

...Also if we turn on the compiler optimization (/Ox option) the optimized code will not overflow the stack and will work correctly instead:

```asm
?f@@YAXXZ PROC ; f
; Line 2
$L3@f:
    jmp     SHORT $L3@f
?f@@YAXXZ ENDP ; f
```

GCC 4.4.1 generates similar code in both cases without, however, issuing any warning about the problem.

ARM

ARM programs also use the stack for saving return addresses, but differently. As mentioned in “Hello, world!” (1.5.3 on page 18), the RA is saved to the LR (link register). If one needs, however, to call another function and use the LR register one more time, its value has to be saved. Usually it is saved in the function prologue.

58 irony here
Often, we see instructions like `PUSH R4-R7,LR` along with this instruction in epilogue `POP R4-R7,PC`—thus register values to be used in the function are saved in the stack, including LR.

Nevertheless, if a function never calls any other function, in RISC terminology it is called a **leaf function**\(^{59}\). As a consequence, leaf functions do not save the LR register (because they don't modify it). If such function is small and uses a small number of registers, it may not use the stack at all. Thus, it is possible to call leaf functions without using the stack, which can be faster than on older x86 machines because external RAM is not used for the stack \(^{60}\). This can be also useful for situations when memory for the stack is not yet allocated or not available.

Some examples of leaf functions: 1.14.3 on page 103, 1.14.3 on page 103, 1.281 on page 318, 1.297 on page 336, 1.28.5 on page 336, 1.191 on page 212, 1.189 on page 210, 1.208 on page 228.

### Passing function arguments

The most popular way to pass parameters in x86 is called “cdecl”:

```plaintext
push arg3
push arg2
push arg1
call f
add esp, 12 ; 4*3=12
```

Callee functions get their argument values via the stack pointer.

Therefore, this is how the argument values are located in the stack before the execution of the `f()` function’s very first instruction:

<table>
<thead>
<tr>
<th>ESP</th>
<th>return address</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP+4</td>
<td>argument#1, marked in IDA as arg_0</td>
</tr>
<tr>
<td>ESP+8</td>
<td>argument#2, marked in IDA as arg_4</td>
</tr>
<tr>
<td>ESP+0xC</td>
<td>argument#3, marked in IDA as arg_8</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

For more information on other calling conventions see also section (6.1 on page 733).

By the way, the callee function does not have any information about how many arguments were passed. C functions with a variable number of arguments (like `printf()`) determine their number using format string specifiers (which begin with the `%` symbol).

If we write something like:

```plaintext
printf("%d %d %d", 1234);
```

`printf()` will print 1234, and then two random numbers\(^{61}\), which were lying next to it in the stack.

That's why it is not very important how we declare the `main()` function: as `main()`, `main(int argc, char *argv[])` or `main(int argc, char *argv[], char *envp[])`.

In fact, the CRT-code is calling `main()` roughly as:

```plaintext
push envp
push argv
push argc
call main
...
```

If you declare `main()` as `main()` without arguments, they are, nevertheless, still present in the stack, but are not used. If you declare `main()` as `main(int argc, char *argv[])`, you will be able to use first two arguments, and the third will remain “invisible” for your function. Even more, it is possible to declare `main(int argc)`, and it will work.

---

\(^{59}\) infocenter.arm.com/help/index.jsp?topic=/com.arm.doc.faqs/ka13785.html

\(^{60}\) Some time ago, on PDP-11 and VAX, the CALL instruction (calling other functions) was expensive; up to 50% of execution time might be spent on it, so it was considered that having a big number of small functions is an **anti-pattern** [Eric S. Raymond, *The Art of UNIX Programming*, (2003)Chapter 4, Part II].

\(^{61}\) Not random in strict sense, but rather unpredictable: 1.9.4 on page 37

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Alternative ways of passing arguments

It is worth noting that nothing obliges programmers to pass arguments through the stack. It is not a requirement. One could implement any other method without using the stack at all.

A somewhat popular way among assembly language newbies is to pass arguments via global variables, like:

Listing 1.38: Assembly code

```assembly
... 
  mov  X, 123
  mov  Y, 456
  call do_something
... 
X dd ?
Y dd ?
do_something proc near
  ; take X
  ; take Y
  ; do something
  retn
do_something endp
```

But this method has obvious drawback: `do_something()` function cannot call itself recursively (or via another function), because it has to zap its own arguments. The same story with local variables: if you hold them in global variables, the function couldn’t call itself. And this is also not thread-safe. A method to store such information in stack makes this easier—it can hold as many function arguments and/or values, as much space it has.

MS-DOS had a way of passing all function arguments via registers, for example, this is piece of code for ancient 16-bit MS-DOS prints “Hello, world!”:

```assembly
mov dx, msg ; address of message
mov ah, 9 ; 9 means "print string" function
int 21h ; DOS "syscall"

mov ah, 4ch ; "terminate program" function
int 21h ; DOS "syscall"

msg db 'Hello, World!\n$
```

This is quite similar to 6.1.3 on page 734 method. And also it’s very similar to calling syscalls in Linux (6.3.1 on page 747) and Windows.

If a MS-DOS function is going to return a boolean value (i.e., single bit, usually indicating error state), CF flag was often used.

For example:

```assembly
mov ah, 3ch ; create file
lea dx, filename
mov cl, 1
int 21h
jc error
mov file_handle, ax
...
error:
...
```

In case of error, CF flag is raised. Otherwise, handle of newly created file is returned via AX.

---

62 Correctly implemented, each thread would have its own stack with its own arguments/variables.
This method is still used by assembly language programmers. In Windows Research Kernel source code (which is quite similar to Windows 2003) we can find something like this (file base/ntos/ke/i386/cpu.asm):

```
public Get386Stepping
Get386Stepping proc
    call MultiplyTest ; Perform multiplication test
    jnc short G3s00 ; if nc, muttest is ok
    mov ax, 0
    ret
G3s00:
    call Check386B0 ; Check for B0 stepping
    jnc short G3s05 ; if nc, it's B1/later
    mov ax, 100h ; It is B0/earlier stepping
    ret
G3s05:
    call Check386D1 ; Check for D1 stepping
    jc short G3s10 ; if c, it is NOT D1
    mov ax, 301h ; It is D1/later stepping
    ret
G3s10:
    mov ax, 101h ; assume it is B1 stepping
    ret
    ...
MultiplyTest proc
    xor cx,cx ; 64K times is a nice round number
mlt00:
    push cx
    call Multiply ; does this chip's multiply work?
    pop cx
    jc short mltx ; if c, No, exit
    loop mlt00 ; if nc, YEs, loop to try again
    clc
    mltx:
    ret
MultiplyTest endp
```

Local variable storage

A function could allocate space in the stack for its local variables just by decreasing the stack pointer towards the stack bottom. Hence, it’s very fast, no matter how many local variables are defined. It is also not a requirement to store local variables in the stack. You could store local variables wherever you like, but traditionally this is how it’s done.

x86: alloc() function

It is worth noting the alloc() function. This function works like malloc(), but allocates memory directly on the stack. The allocated memory chunk does not have to be freed via a free() function call, since the function epilogue (1.6 on page 28) returns ESP back to its initial state and the allocated memory is just dropped. It is worth noting how alloc() is implemented. In simple terms, this function just shifts ESP downwards toward the stack bottom by the number of bytes you need and sets ESP as a pointer to the allocated block.

Let’s try:

```
#ifdef __GNUC__
#include <alloca.h> // GCC
#endif
```

---

63In MSVC, the function implementation can be found in alloc16.asm and chkstk.asm in C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\crt\src\intel

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
else
#include <malloc.h> // MSVC
endif
#include <stdio.h>

void f()
{
    char *buf=(char*)alloca (600);
#ifdef __GNUC__
    snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // GCC
#else
    _snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // MSVC
#endif
    puts (buf);
};

_snprintf() function works just like printf(), but instead of dumping the result into stdout (e.g., to terminal or console), it writes it to the buf buffer. Function puts() copies the contents of buf to stdout. Of course, these two function calls might be replaced by one printf() call, but we have to illustrate small buffer usage.

**MSVC**

Let's compile (MSVC 2010):

Listing 1.39: MSVC 2010

```assembly
... mov   eax, 600 ; 00000258H call  __alloca_probe_16 mov   esi, esp push  3 push  2 push  1 pushOFFSET $SG2672 push 600 ; 00000258H push esi call  __snprintf push esi call  _puts add   esp, 28 ...
```

The sole alloca() argument is passed via EAX (instead of pushing it into the stack) 64.

**GCC + Intel syntax**

GCC 4.4.1 does the same without calling external functions:

Listing 1.40: GCC 4.7.3

```assembly
.LCO: .string "hi! %d, %d, %d\n"
f:       push   ebp mov    ebp, esp push   ebx
```

64It is because alloca() is rather a compiler intrinsic (11.3 on page 972) than a normal function. One of the reasons we need a separate function instead of just a couple of instructions in the code, is because the MSVC alloca() implementation also has code which reads from the memory just allocated, in order to let the OS map physical memory to this VM region. After the alloca() call, ESP points to the block of 600 bytes and we can use it as memory for the buf array.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
sub    esp, 660
lea    ebx, [esp+39] ; align pointer by 16-bit border
and    ebx, -16
mov    DWORD PTR [esp], ebx ; s
mov    DWORD PTR [esp+20], 3
mov    DWORD PTR [esp+16], 2
mov    DWORD PTR [esp+12], 1
mov    DWORD PTR [esp+8], OFFSET FLAT:.LC0 ; "hi! %d, %d, %d\n"
mov    DWORD PTR [esp+4], 600 ; maxlen
call   _snprintf
mov    DWORD PTR [esp], ebx ; s
call   puts
mov    ebx, DWORD PTR [ebp-4]
leave
ret

GCC + AT&T syntax

Let's see the same code, but in AT&T syntax:

Listing 1.41: GCC 4.7.3

.LC0:
.string "hi! %d, %d, %d\n"
f:
pushl %ebp
movl %esp, %ebp
pushl %ebx
subl $660, %esp
leal 39(%esp), %ebx
andl $-16, %ebx
movl %ebx, (%esp)
movl $3, 20(%esp)
movl $2, 16(%esp)
movl $1, 12(%esp)
movl $.LC0, 8(%esp)
movl $600, 4(%esp)
call   _snprintf
movl %ebx, (%esp)
call   puts
movl -4(%ebp), %ebx
leave
ret

The code is the same as in the previous listing.

By the way, movl $3, 20(%esp) corresponds to mov DWORD PTR [esp+20], 3 in Intel-syntax. In the AT&T syntax, the register+offset format of addressing memory looks like offset(%register).

(Windows) SEH

SEH records are also stored on the stack (if they are present). Read more about it: (6.5.3 on page 764).

Buffer overflow protection

More about it here (1.26.2 on page 275).

Automatic deallocation of data in stack

Perhaps the reason for storing local variables and SEH records in the stack is that they are freed automatically upon function exit, using just one instruction to correct the stack pointer (it is often ADD). Function

\[^{67}\text{Structured Exception Handling}\]

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
arguments, as we could say, are also deallocated automatically at the end of function. In contrast, everything stored in the heap must be deallocated explicitly.

1.9.3 A typical stack layout

A typical stack layout in a 32-bit environment at the start of a function, before the first instruction execution looks like this:

<table>
<thead>
<tr>
<th>ESP-0xC</th>
<th>local variable#2, marked in IDA as var_8</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP-8</td>
<td>local variable#1, marked in IDA as var_4</td>
</tr>
<tr>
<td>ESP-4</td>
<td>saved value of EBP</td>
</tr>
<tr>
<td>ESP</td>
<td>Return Address</td>
</tr>
<tr>
<td>ESP+4</td>
<td>argument#1, marked in IDA as arg_0</td>
</tr>
<tr>
<td>ESP+8</td>
<td>argument#2, marked in IDA as arg_4</td>
</tr>
<tr>
<td>ESP+0xC</td>
<td>argument#3, marked in IDA as arg_8</td>
</tr>
</tbody>
</table>

1.9.4 Noise in stack

When one says that something seems random, what one usually means in practice is that one cannot see any regularities in it.

Stephen Wolfram, A New Kind of Science.

Often in this book “noise” or “garbage” values in the stack or memory are mentioned. Where do they come from? These are what has been left there after other functions’ executions. Short example:

```c
#include <stdio.h>

void f1()
{
    int a=1, b=2, c=3;
}

void f2()
{
    int a, b, c;
    printf("%d, %d, %d\n", a, b, c);
}

int main()
{
    f1();
    f2();
}
```

Compiling ...

Listing 1.42: Non-optimizing MSVC 2010

<table>
<thead>
<tr>
<th>SG2752 DB</th>
<th>%d, %d, %d', 0aH, 00H</th>
</tr>
</thead>
<tbody>
<tr>
<td>_c$ = .-12</td>
<td>; size = 4</td>
</tr>
<tr>
<td>_b$ = .-8</td>
<td>; size = 4</td>
</tr>
<tr>
<td>_a$ = .-4</td>
<td>; size = 4</td>
</tr>
<tr>
<td>_f1 PROC</td>
<td>push ebp</td>
</tr>
<tr>
<td></td>
<td>mov ebp, esp</td>
</tr>
<tr>
<td></td>
<td>sub esp, 12</td>
</tr>
<tr>
<td></td>
<td>mov DWORD PTR _a$[ebp], 1</td>
</tr>
<tr>
<td></td>
<td>mov DWORD PTR _b$[ebp], 2</td>
</tr>
<tr>
<td></td>
<td>mov DWORD PTR _c$[ebp], 3</td>
</tr>
<tr>
<td></td>
<td>mov esp, ebp</td>
</tr>
<tr>
<td></td>
<td>pop ebp</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The compiler will grumble a little bit...

```

/out:st.exe
st.obj
```

But when we run the compiled program ...

```
c:\Polygon\c>st
1, 2, 3
```

Oh, what a weird thing! We did not set any variables in f2(). These are “ghosts” values, which are still in the stack.
Let's load the example into OllyDbg:

![OllyDbg](image)

When \( f1() \) assigns the variables \( a, b \) and \( c \), their values are stored at the address \( 0x1FF860 \) and so on.
And when \( f2() \) executes:

**Figure 1.7: OllyDbg: f2()**

... \( a \), \( b \) and \( c \) of \( f2() \) are located at the same addresses! No one has overwritten the values yet, so at that point they are still untouched. So, for this weird situation to occur, several functions have to be called one after another and **SP** has to be the same at each function entry (i.e., they have the same number of arguments). Then the local variables will be located at the same positions in the stack. Summarizing, all values in the stack (and memory cells in general) have values left there from previous function executions. They are not random in the strict sense, but rather have unpredictable values. Is there another option? It would probably be possible to clear portions of the stack before each function execution, but that’s too much extra (and unnecessary) work.

**MSVC 2013**

The example was compiled by MSVC 2010. But the reader of this book made attempt to compile this example in MSVC 2013, ran it, and got all 3 numbers reversed:

```
c:\Polygon\c\st
3, 2, 1
```

Why? I also compiled this example in MSVC 2013 and saw this:

**Listing 1.43: MSVC 2013**

```assembly
.a$ = -12 ; size = 4
.b$ = -8 ; size = 4
.c$ = -4 ; size = 4
.f2 PROC
...
.f2 ENDP
.c$ = -12 ; size = 4
.b$ = -8 ; size = 4
.a$ = -4 ; size = 4
.f1 PROC
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Unlike MSVC 2010, MSVC 2013 allocated a/b/c variables in function f2() in reverse order. And this is completely correct, because C/C++ standards has no rule, in which order local variables must be allocated in the local stack, if at all. The reason of difference is because MSVC 2010 has one way to do it, and MSVC 2013 has supposedly something changed inside of compiler guts, so it behaves slightly different.

1.9.5 Exercises

- http://challenges.re/51
- http://challenges.re/52

1.10 Almost empty function

This is a real piece of code I found in Boolector:

```c
// forward declaration. the function is residing in some other module:
int boolector_main (int argc, char **argv);

// executable
int main (int argc, char **argv)
{
    return boolector_main (argc, argv);
}
```

Why would anyone do so? I don’t know, but my best guess is that boolector_main() may be compiled in some kind of DLL or dynamic library, and be called from a test suite. Surely, a test suite can prepare argc/argv variables as CRT would do it.

Interestingly enough, how this compiles:

Listing 1.44: Non-optimizing GCC 8.2 x64 (assembly output)

```
main:
push    rbp
mov     rbp, rsp
sub     rsp, 16
mov     DWORD PTR -4[rbp], edi
mov     DWORD PTR -4[rbp], rsi
mov     rdx, QWORD PTR -16[rbp]
mov     eax, DWORD PTR -4[rbp]
mov     rsi, rdx
mov     edi, eax
call    boolector_main
leave
ret
```

This is OK, prologue, unnecessary (not optimized) shuffling of two arguments, CALL, epilogue, RET. But let’s see optimizing version:

Listing 1.45: Optimizing GCC 8.2 x64 (assembly output)

```
main:
jmp     boolector_main
```

As simple as that: stack/registers are untouched and boolector_main() has the same arguments set. So all we need to do is pass execution to another address.

This is close to thunk function.

We will see something more advanced later: 1.11.2 on page 54, 1.21.1 on page 156.

---

68 https://boolector.github.io/
Now let's extend the Hello, world! (1.5 on page 8) example, replacing printf() in the main() function body with this:

```c
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d", 1, 2, 3);
    return 0;
}
```

### 1.11.1 x86

**x86: 3 arguments**

**MSVC**

When we compile it with MSVC 2010 Express we get:

```assembly
SG3830 DB 'a=%d; b=%d; c=%d', 00H
...
push 3
push 2
push 1
push OFFSET $SG3830
call _printf
add esp, 16 ; 00000010H
```

Almost the same, but now we can see the `printf()` arguments are pushed onto the stack in reverse order. The first argument is pushed last.

By the way, variables of `int` type in 32-bit environment have 32-bit width, that is 4 bytes.

So, we have 4 arguments here. $4 \times 4 = 16$ — they occupy exactly 16 bytes in the stack: a 32-bit pointer to a string and 3 numbers of type `int`.

When the stack pointer (ESP register) has changed back by the ADD ESP, X instruction after a function call, often, the number of function arguments could be deduced by simply dividing X by 4.

Of course, this is specific to the cdecl calling convention, and only for 32-bit environment.

See also the calling conventions section (6.1 on page 733).

In certain cases where several functions return right after one another, the compiler could merge multiple “ADD ESP, X” instructions into one, after the last call:

```assembly
push a1
push a2
call ...
...
push a1
call ...
...
push a1
push a2
push a3
call ...
add esp, 24
```

Here is a real-world example:
Listing 1.46: x86

.text:100113E7 push 3
.text:100113E9 call sub_100018B0 ; takes one argument (3)
.text:100113EE call sub_100019D0 ; takes no arguments at all
.text:100113F3 call sub_10006A90 ; takes no arguments at all
.text:100113F8 push 1
.text:100113FA call sub_100018B0 ; takes one argument (1)
.text:100113FF add esp, 8 ; drops two arguments from stack at once
Now let's try to load this example in OllyDbg. It is one of the most popular user-land win32 debuggers. We can compile our example in MSVC 2012 with /MD option, which means to link with MSVCR*.DLL, so we can see the imported functions clearly in the debugger.

Then load the executable in OllyDbg. The very first breakpoint is in ntdll.dll, press F9 (run). The second breakpoint is in CRT-code. Now we have to find the main() function.

Find this code by scrolling the code to the very top (MSVC allocates the main() function at the very beginning of the code section):

Click on the PUSH EBP instruction, press F2 (set breakpoint) and press F9 (run). We have to perform these actions in order to skip CRT-code, because we aren't really interested in it yet.
Press F8 (step over) 6 times, i.e. skip 6 instructions:

Now the PC points to the CALL printf instruction. OllyDbg, like other debuggers, highlights the value of the registers which were changed. So each time you press F8, EIP changes and its value is displayed in red. ESP changes as well, because the arguments values are pushed into the stack.

Where are the values in the stack? Take a look at the right bottom debugger window:

We can see 3 columns there: address in the stack, value in the stack and some additional OllyDbg comments. OllyDbg understands printf()-like strings, so it reports the string here and the 3 values attached to it.

It is possible to right-click on the format string, click on “Follow in dump”, and the format string will appear in the debugger left-bottom window, which always displays some part of the memory. These memory values can be edited. It is possible to change the format string, in which case the result of our example would be different. It is not very useful in this particular case, but it could be good as an exercise so you start building a feel of how everything works here.
Press F8 (step over).

We see the following output in the console:

\[
a = 1; \quad b = 2; \quad c = 3
\]

Let’s see how the registers and stack state have changed:

---

**Figure 1.11: OllyDbg after printf() execution**

Register EAX now contains 0xD (13). That is correct, since printf() returns the number of characters printed. The value of EIP has changed: indeed, now it contains the address of the instruction coming after CALL printf. ECX and EDX values have changed as well. Apparently, the printf() function’s hidden machinery used them for its own needs.

A very important fact is that neither the ESP value, nor the stack state have been changed! We clearly see that the format string and corresponding 3 values are still there. This is indeed the cdecl calling convention behavior: callee does not return ESP back to its previous value. The caller is responsible to do so.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Press F8 again to execute ADD ESP, 10 instruction:

![CPU - main thread, module 1]

Figure 1.12: OllyDbg: after ADD ESP, 10 instruction execution

ESP has changed, but the values are still in the stack! Yes, of course; no one needs to set these values to zeros or something like that. Everything above the stack pointer (SP) is noise or garbage and has no meaning at all. It would be time consuming to clear the unused stack entries anyway, and no one really needs to.

GCC

Now let's compile the same program in Linux using GCC 4.4.1 and take a look at what we have got in IDA:

```c
main proc near
var_10 = dword ptr -10h
var_C = dword ptr -0Ch
var_8 = dword ptr -8
var_4 = dword ptr -4

push ebp
mov ebp, esp
and esp, 0FFFFFFF0h
sub esp, 10h
mov eax, offset aADBDCD ; "a=%d; b=%d; c=%d"
mov [esp+10h+var_4], 3
mov [esp+10h+var_8], 2
mov [esp+10h+var_C], 1
mov [esp+10h+var_10], eax
call __printf
mov eax, 0
leave
retn

main endp
```

It's noticeable that the difference between the MSVC code and the GCC code is only in the way the arguments are stored on the stack. Here the GCC is working directly with the stack without the use of PUSH/POP.

GCC and GDB

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Let's try this example also in **GDB** in Linux.

- `g` option instructs the compiler to include debug information in the executable file.

```bash
$ gcc 1.c -g -o 1
```

```bash
$ gdb 1
GNU gdb (GDB) 7.6.1-ubuntu
...
Reading symbols from /home/dennis/polygon/1...done.
```

Listing 1.47: let's set breakpoint on `printf()`

```
(gdb) b printf
Breakpoint 1 at 0x80482f0
```

Run. We don't have the `printf()` function source code here, so **GDB** can't show it, but may do so.

```
(gdb) run
Starting program: /home/dennis/polygon/1
Breakpoint 1, __printf (format=0x80484f0 "a=%d; b=%d; c=%d") at printf.c:29
29 printf.c: No such file or directory.
```

Print 10 stack elements. The most left column contains addresses on the stack.

```
(gdb) x/10w $esp
0xbffff11c: 0x0804844a 0x080484f0 0x00000001 0x00000002
0xbffff12c: 0x00000003 0x08048460 0x00000000 0x00000000
0xbffff13c: 0xb7e29905 0x00000001
```

The very first element is the **RA** (0x0804844a). We can verify this by disassembling the memory at this address:

```
(gdb) x/5i 0x0804844a
0x804844a <main+45>: mov $0x0,%eax
0x804844f <main+50>: leave
0x8048450 <main+51>: ret
0x8048451: xchg %ax,%ax
0x8048453: xchg %ax,%ax
```

The two **XCHG** instructions are idle instructions, analogous to **NOPs**.

The second element (0x080484f0) is the format string address:

```
(gdb) x/s 0x080484f0
0x080484f0: "a=%d; b=%d; c=%d"
```

Next 3 elements (1, 2, 3) are the `printf()` arguments. The rest of the elements could be just "garbage" on the stack, but could also be values from other functions, their local variables, etc. We can ignore them for now.

Run “finish”. The command instructs **GDB** to “execute all instructions until the end of the function”. In this case: execute till the end of `printf()`.

```
(gdb) finish
Run till exit from #0 __printf (format=0x80484f0 "a=%d; b=%d; c=%d") at printf.c:29
main () at 1.c:6
6 return 0;
Value returned is $2 = 13
```

**GDB** shows what `printf()` returned in **EAX** (13). This is the number of characters printed out, just like in the OllyDbg example.

We also see “return 0;” and the information that this expression is in the `1.c` file at the line 6. Indeed, the `1.c` file is located in the current directory, and **GDB** finds the string there. How does **GDB** know which C-code line is being currently executed? This is due to the fact that the compiler, while generating

---

69GNU Debugger

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
debugging information, also saves a table of relations between source code line numbers and instruction addresses. GDB is a source-level debugger, after all.

Let’s examine the registers. 13 in EAX:

```
(gdb) info registers
eax 0xd 13
cx 0x0 0
dx 0x0 0
ebx 0xb7fc0000 -1208221696
esp 0xbffff120 0xbffff120
ebp 0xbffff138 0xbffff138
esi 0x0 0
edi 0x0 0
eip 0x804844a 0x804844a <main+45>
...
```

Let’s disassemble the current instructions. The arrow points to the instruction to be executed next.

```
(gdb) disas
Dump of assembler code for function main:
  0x0804841d <+0>: push %ebp
  0x0804841e <+1>: mov %esp,%ebp
  0x08048420 <+3>: and $0xfffffff0,%esp
  0x08048423 <+6>: sub $0x10,%esp
  0x08048426 <+9>: movl $0x3,0xc(%esp)
  0x0804842e <+17>: movl $0x2,0x8(%esp)
  0x08048436 <+25>: movl $0x1,0x4(%esp)
  0x0804843e <+33>: movl $0x80484f0,(%esp)
  0x08048445 <+40>: call 0x80482f0 <printf@plt>
 => 0x0804844a <+45>: mov $0x0,%eax
  0x0804844f <+50>: leave
  0x08048450 <+51>: ret
End of assembler dump.
```

**GDB** uses AT&T syntax by default. But it is possible to switch to Intel syntax:

```
(gdb) set disassembly-flavor intel
(gdb) disas
Dump of assembler code for function main:
  0x0804841d <+0>: push ebp
  0x0804841e <+1>: mov ebp,esp
  0x08048420 <+3>: and esp,0xffffff0
  0x08048423 <+6>: sub esp,0x10
  0x08048426 <+9>: mov DWORD PTR [esp+0xc],0x3
  0x0804842e <+17>: mov DWORD PTR [esp+0x8],0x2
  0x08048436 <+25>: mov DWORD PTR [esp+0x4],0x1
  0x0804843e <+33>: mov DWORD PTR [esp],0x80484f0
  0x08048445 <+40>: call 0x80482f0 <printf@plt>
 => 0x0804844a <+45>: mov eax,0x0
  0x0804844f <+50>: leave
  0x08048450 <+51>: ret
End of assembler dump.
```

Execute next instruction. **GDB** shows ending bracket, meaning, it ends the block.

```
(gdb) step
7 }
```

Let’s examine the registers after the MOV EAX, 0 instruction execution. Indeed EAX is zero at that point.

```
(gdb) info registers
eax 0x0 0
cx 0x0 0
dx 0x0 0
ebx 0xb7fc0000 -1208221696
esp 0xbffff120 0xbffff120
ebp 0xbffff138 0xbffff138
esi 0x0 0
edi 0x0 0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
x64: 8 arguments

To see how other arguments are passed via the stack, let’s change our example again by increasing the number of arguments to 9 (printf() format string + 8 int variables):

```c
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n", 1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
};
```

MSVC

As it was mentioned earlier, the first 4 arguments has to be passed through the RCX, RDX, R8, R9 registers in Win64, while all the rest—via the stack. That is exactly what we see here. However, the MOV instruction, instead of PUSH, is used for preparing the stack, so the values are stored to the stack in a straightforward manner.

Listing 1.48: MSVC 2012 x64

```assembly
$SG2923 DB 'a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d', 0aH, 00H

main PROC
    sub    rsp, 88
    mov    DWORD PTR [rsp+64], 8
    mov    DWORD PTR [rsp+56], 7
    mov    DWORD PTR [rsp+48], 6
    mov    DWORD PTR [rsp+40], 5
    mov    DWORD PTR [rsp+32], 4
    mov    r9d, 3
    mov    r8d, 2
    mov    edx, 1
    lea    rcx, OFFSET FLAT:$SG2923
    call   printf

    ; return 0
    xor    eax, eax
    add    rsp, 88
    ret

main ENDP
TEXT ENDS
END
```

The observant reader may ask why are 8 bytes allocated for int values, when 4 is enough? Yes, one has to recall: 8 bytes are allocated for any data type shorter than 64 bits. This is established for the convenience’s sake: it makes it easy to calculate the address of arbitrary argument. Besides, they are all located at aligned memory addresses. It is the same in the 32-bit environments: 4 bytes are reserved for all data types.

GCC

The picture is similar for x86-64 *NIX OS-es, except that the first 6 arguments are passed through the RDI, RSI, RDX, RCX, R8, R9 registers. All the rest—via the stack. GCC generates the code storing the string pointer into EDI instead of RDI—we noted that previously: 1.5.2 on page 16.

We also noted earlier that the EAX register has been cleared before a printf() call: 1.5.2 on page 16.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.49: Optimizing GCC 4.4.6 x64

.LC0:
.string "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n"

main:
    sub rsp, 40
    mov r9d, 5
    mov r8d, 4
    mov ecx, 3
    mov edx, 2
    mov esi, 1
    mov edi, OFFSET FLAT:.LC0
    xor eax, eax ; number of vector registers passed
    mov DWORD PTR [rsp+16], 8
    mov DWORD PTR [rsp+8], 7
    mov DWORD PTR [rsp], 6
    call printf

    ; return 0
    xor eax, eax
    add rsp, 40
    ret

GCC + GDB

Let's try this example in GDB.

$ gcc -g 2.c -o 2

$ gdb 2
GNU gdb (GDB) 7.6.1-ubuntu
...Reading symbols from /home/dennis/polygon/2...done.

Listing 1.50: let's set the breakpoint to printf(), and run

(gdb) b printf
Breakpoint 1 at 0x400410
(gdb) run
Starting program: /home/dennis/polygon/2
Breakpoint 1, __printf (format=0x400628 "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n") at printf.c:29
29 printf.c: No such file or directory.

Registers RSI/RDX/RCX/R8/R9 have the expected values. RIP has the address of the very first instruction of the printf() function.

(gdb) info registers
rax 0x0 0
rbx 0x0 0
rcx 0x3 3
rdx 0x2 2
rsi 0x1 1
rdi 0x400628 4195880
rbp 0x7ffffffdf60 0x7ffffffdf60
rsp 0x7ffffffdf38 0x7ffffffdf38
r8 0x4 4
r9 0x5 5
r10 0x7ffffffdce0 140737488346336
r11 0x7fffffff7a65f60 140737348263776
r12 0x400440 4195392
r13 0x7fffffffffe040 140737488347200
r14 0x0 0
r15 0x0 0

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's inspect the format string

```
Listing 1.51: let’s inspect the format string
(gdb) x/s $rdi
0x400628: "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n"
```

Let's dump the stack with the x/g command this time—g stands for giant words, i.e., 64-bit words.

```
(gdb) x/10g $rsp
0x7fffffffdf38: 0x0000000000400576 0x0000000000000006
0x7fffffffdf48: 0x0000000000000007 0x00007ffe00000008
0x7fffffffdf58: 0x0000000000000000 0x0000000000000000
0x7fffffffdf68: 0x00007ffff7a33de5 0x0000000000000000
0x7fffffffdf78: 0x00007fffffffe048 0x0000000100000000
```

The very first stack element, just like in the previous case, is the RA. 3 values are also passed through the stack: 6, 7, 8. We also see that 8 is passed with the high 32-bits not cleared: 0x00007ffe00000008. That's OK, because the values are of int type, which is 32-bit. So, the high register or stack element part may contain “random garbage”.

If you take a look at where the control will return after the printf() execution, GDB will show the entire main() function:

```
(gdb) set disassembly-flavor intel
(gdb) disas 0x0000000000400576
Dump of assembler code for function main:
 0x000000000040052d <+0>: push rbp
 0x000000000040052e <+1>: mov rbp,rsp
 0x0000000000400531 <+4>: sub rsp,0x20
 0x0000000000400535 <+8>: mov DWORD PTR [rsp+0x10],0x8
 0x000000000040053d <+16>: mov DWORD PTR [rsp+0x8],0x7
 0x0000000000400545 <+24>: mov DWORD PTR [rsp],0x6
 0x000000000040054c <+31>: mov r9d,0x5
 0x0000000000400552 <+37>: mov r8d,0x4
 0x0000000000400558 <+43>: mov ecx,0x3
 0x000000000040055d <+48>: mov edx,0x2
 0x0000000000400562 <+53>: mov esi,0x1
 0x0000000000400567 <+58>: mov edi,0x400628
 0x000000000040056c <+63>: mov eax,0x0
 0x0000000000400571 <+68>: call 0x400410 <printf@plt>
 0x0000000000400576 <+73>: mov eax,0x0
 0x000000000040057b <+78>: leave
 0x000000000040057c <+79>: ret
End of assembler dump.
```

Let's finish executing printf(), execute the instruction zeroing EAX, and note that the EAX register has a value of exactly zero. RIP now points to the LEAVE instruction, i.e., the penultimate one in the main() function.

```
(gdb) finish
Run till exit from #0 __printf (format=0x400628 "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n") at printf.c:29
a=1; b=2; c=3; d=4; e=5; f=6; g=7; h=8

1.11.2 ARM

ARM: 3 arguments

ARM's traditional scheme for passing arguments (calling convention) behaves as follows: the first 4 arguments are passed through the R0-R3 registers; the remaining arguments via the stack. This resembles the arguments passing scheme infastcall (6.1.3 on page 734) or win64 (6.1.5 on page 736).

32-bit ARM

Non-optimizing Keil 6/2013 (ARM mode)

```
Listing 1.52: Non-optimizing Keil 6/2013 (ARM mode)
.text:00000000 main
.text:00000000 10 40 2D E9 STMFD SP!, {R4,LR}
.text:00000004 03 30 A0 E3 MOV R3, #3
.text:00000008 02 20 A0 E3 MOV R2, #2
.text:0000000C 01 10 A0 E3 MOV R1, #1
.text:00000010 08 00 8F E2 ADR R0, aADBDCD ; "a=%d; b=%d; c=%d"
.text:00000014 06 00 00 EB BL __2printf
.text:00000018 00 00 A0 E3 MOV R0, #0 ; return 0
.text:0000001C 10 80 BD E8 LDMFD SP!, {R4,PC}
```

So, the first 4 arguments are passed via the R0-R3 registers in this order: a pointer to the printf() format string in R0, then 1 in R1, 2 in R2 and 3 in R3. The instruction at 0x18 writes 0 to R0—this is return 0 C-statement. There is nothing unusual so far.

Optimizing Keil 6/2013 generates the same code.

Optimizing Keil 6/2013 (Thumb mode)

```
Listing 1.53: Optimizing Keil 6/2013 (Thumb mode)
.text:00000000 main
.text:00000000 10 B5 PUSH {R4,LR}
.text:00000002 03 23 MOV R3, #3
.text:00000004 02 22 MOV R2, #2
.text:00000006 01 21 MOV R1, #1
.text:00000008 02 A0 ADR R0, aADBDCD ; "a=%d; b=%d; c=%d"
.text:0000000A 00 F0 0D F8 BL __2printf
.text:0000000E 00 20 MOV R0, #0
.text:00000010 10 BD POP {R4,PC}
```

There is no significant difference from the non-optimized code for ARM mode.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's rework example slightly by removing `return 0`:

```c
#include <stdio.h>

void main()
{
    printf("a=%d; b=%d; c=%d", 1, 2, 3);
}
```

The result is somewhat unusual:

Listing 1.54: Optimizing Keil 6/2013 (ARM mode)

```
.text:00000014 main
.text:00000014 03 30 A0 E3 MOV R3, #3
.text:00000018 02 20 A0 E3 MOV R2, #2
.text:0000001C 01 10 A0 E3 MOV R1, #1
.text:00000020 1E 0E 8F E2 ADR R0, aADBD0CD ; "a=%d; b=%d; c=%d\n"
.text:00000024 CB 18 00 EA B __2printf
```

This is the optimized (-O3) version for ARM mode and this time we see `B` as the last instruction instead of the familiar `BL`. Another difference between this optimized version and the previous one (compiled without optimization) is the lack of function prologue and epilogue (instructions preserving the R0 and LR registers values). The `B` instruction just jumps to another address, without any manipulation of the LR register, similar to JMP in x86. Why does it work? Because this code is, in fact, effectively equivalent to the previous. There are two main reasons: 1) neither the stack nor SP (the stack pointer) is modified; 2) the call to printf() is the last instruction, so there is nothing going on afterwards. On completion, the printf() function simply returns the control to the address stored in LR. Since the LR currently stores the address of the point from where our function has been called then the control from printf() will be returned to that point. Therefore we do not have to save LR because we do not have necessity to modify LR. And we do not have necessity to modify LR because there are no other function calls except printf(). Furthermore, after this call we do not to do anything else! That is the reason such optimization is possible.

This optimization is often used in functions where the last statement is a call to another function. A similar example is presented here: 1.21.1 on page 156.

A somewhat simpler case was described above: 1.10 on page 41.

**ARM64**

**Non-optimizing GCC (Linaro) 4.9**

Listing 1.55: Non-optimizing GCC (Linaro) 4.9

```
.LC1:
    .string "a=%d; b=%d; c=%d"

f2:
    ; save FP and LR in stack frame:
    stp   x29, x30, [sp, -16]!
    ; set stack frame (FP=SP):
    add   x29, sp, 0
    adrp  x0, .LC1
    add   x0, x0, :lo12:.LC1
    mov   w1, 1
    mov   w2, 2
    mov   w3, 3
    bl    printf
    mov   w0, 0
    ; restore FP and LR
    ldp   x29, x30, [sp], 16
    ret
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The first instruction STP (Store Pair) saves FP (X29) and LR (X30) in the stack. The second ADD X29, SP, 0 instruction forms the stack frame. It is just writing the value of SP into X29.

Next, we see the familiar ADRP/ADD instruction pair, which forms a pointer to the string. lo12 meaning low 12 bits, i.e., linker will write low 12 bits of LC1 address into the opcode of ADD instruction. %d in printf() string format is a 32-bit int, so the 1, 2 and 3 are loaded into 32-bit register parts.

Optimizing GCC (Linaro) 4.9 generates the same code.

ARM: 8 arguments

Let’s use again the example with 9 arguments from the previous section: 1.11.1 on page 50.

```
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n", 1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
}
```

Optimizing Keil 6/2013: ARM mode

```
.text:00000028 main
.text:00000028 var_18 = -0x18
.text:00000028 var_14 = -0x14
.text:00000028 var_4 = -4
.text:00000028
.text:00000028 04 E0 2D E5 STR LR, [SP,#var_4]!
.text:00000028 14 D0 4D E2 SUB SP, SP, #0x14
.text:00000030 08 30 A0 E3 MOV R3, #8
.text:00000034 07 20 A0 E3 MOV R2, #7
.text:00000038 06 10 A0 E3 MOV R1, #6
.text:0000003C 05 00 A0 E3 MOV R0, #5
.text:00000040 04 C0 8D E2 ADD R12, SP, #0x18+var_14
.text:00000044 0F 00 8C E8 STMIA R12, {R0-R3}
.text:00000048 04 00 A0 E3 MOV R0, #4
.text:0000004C 00 00 8D E5 STR R0, [SP,#0x18+var_18]
.text:00000050 03 30 A0 E3 MOV R3, #3
.text:00000054 02 20 A0 E3 MOV R2, #2
.text:00000058 01 10 A0 E3 MOV R1, #1
.text:0000005C 6E 0F 8F E2 ADR R0, aADBDCCDDDFGDFGD ; "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d"
.text:00000060 BC 18 00 EB BL __2printf
.text:00000064 14 D0 8D E2 ADD SP, SP, #0x14
.text:00000068 04 F0 9D E4 LDR PC, [SP+4+var_4],#4
```

This code can be divided into several parts:

- **Function prologue:**

  The very first STR LR, [SP,#var_4]! instruction saves LR on the stack, because we are going to use this register for the printf() call. Exclamation mark at the end indicates pre-index.

  This implies that SP is to be decreased by 4 first, and then LR will be saved at the address stored in SP. This is similar to PUSH in x86. Read more about it at: 1.39.2 on page 444.

  The second SUB SP, SP, #0x14 instruction decreases SP (the stack pointer) in order to allocate 0x14 (20) bytes on the stack. Indeed, we have to pass 5 32-bit values via the stack to the printf() function, and each one occupies 4 bytes, which is exactly 5 \times 4 = 20. The other 4 32-bit values are to be passed through registers.

- **Passing 5, 6, 7 and 8 via the stack:** they are stored in the R0, R1, R2 and R3 registers respectively. Then, the ADD R12, SP, #0x18+var_14 instruction writes the stack address where these 4 variables are to be stored, into the R12 register. var_14 is an assembly macro, equal to -0x14, created by IDA
So, SP+4 is to be stored into the R12 register.

The next STMIA R12, R0-R3 instruction writes registers R0-R3 contents to the memory pointed by R12. STMIA abbreviates Store Multiple Increment After. Increment After implies that R12 is to be increased by 4 after each register value is written.

- Passing 4 via the stack: 4 is stored in R0 and then this value, with the help of the STR R0, [SP,#0x18+var_18] instruction is saved on the stack. var_18 is -0x18, so the offset is to be 0, thus the value from the R0 register (4) is to be written to the address written in SP.

- Passing 1, 2 and 3 via registers: The values of the first 3 numbers (a, b, c) (1, 2, 3 respectively) are passed through the R1, R2 and R3 registers right before the printf() call, and the other 5 values are passed via the stack:
  - printf() call.

- Function epilogue:

The ADD SP, SP, #0x14 instruction restores the SP pointer back to its former value, thus annulling everything what has been stored on the stack. Of course, what has been stored on the stack will stay there, but it will all be rewritten during the execution of subsequent functions.

The LDR PC, [SP+4+var_4],#4 instruction loads the saved LR value from the stack into the PC register, thus causing the function to exit. There is no exclamation mark—indeed, PC is loaded first from the address stored in SP (4+var_4 = 4+(-4) = 0), so this instruction is analogous to LDR PC, [SP],#4, and then SP is increased by 4. This is referred as post-index\(^70\). Why does IDA display the instruction like that? Because it wants to illustrate the stack layout and the fact that var_4 is allocated for saving the LR value in the local stack. This instruction is somewhat similar to POP PC in x86\(^71\).

### Optimizing Keil 6/2013: Thumb mode

```
.text:0000001C  printf_main2
.text:0000001C  var_18 = -0x18
.text:0000001C  var_14 = -0x14
.text:0000001C  var_8 = -8
.text:0000001C  00 B5 Push {LR}
.text:0000001E  08 23 MOVS R3, #8
.text:00000020  85 B0 SUB SP, SP, #0x14
.text:00000022  04 93 STR R3, [SP,#0x18+var_8]
.text:00000024  07 22 MOVS R2, #7
.text:00000026  06 21 MOVS R1, #6
.text:00000028  05 20 MOVS R0, #5
.text:0000002A  01 AB ADD R3, SP, #0x18+var_14
.text:0000002C  07 C3 STMIA R3!, {R0-R2}
.text:0000002E  04 20 MOVS R0, #4
.text:00000030  00 90 STR R0, [SP,#0x18+var_18]
.text:00000032  03 23 MOVS R3, #3
.text:00000034  02 22 MOVS R2, #2
.text:00000036  01 21 MOVS R1, #1
.text:00000038 A0 A0 ADR R0, aABDCDDDEDFFGDG ; "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d"
.text:0000003A  06 F0 D9 F8 BL __2printf
.text:0000003E loc_3E  ; CODE XREF: example13_f+16
.text:0000003E  05 B0 ADD SP, SP, #0x14
.text:0000003E  00 BD POP {PC}
```

The output is almost like in the previous example. However, this is Thumb code and the values are packed into stack differently: 8 goes first, then 5, 6, 7, and 4 goes third.

\(^70\)Read more about it: 1.39.2 on page 444.

\(^71\)It is impossible to set IP/EIP/RIP value using POP in x86, but anyway, you got the analogy right.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Another thing that catches the eye is that the instructions are arranged seemingly random. For example, instructions like
\[
\text{ADD R0, PC, R0}
\]
can be executed simultaneously since the effects of their execution are not conflicting with each other.

Usually, the processor attempts to simultaneously execute instructions located side-by-side. For example, instructions like MOV T R0, #0 and ADD R0, PC, R0 cannot be executed simultaneously since they both modify the R0 register. On the other hand, MOV T R0, #0 and MOV R2, #4 instructions can be executed simultaneously since the effects of their execution are not conflicting with each other. Presumably, the compiler tries to generate code in such a manner (wherever it is possible).

Optimizing Xcode 4.6.3 (LLVM): Thumb-2 mode

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The output is almost the same as in the previous example, with the exception that Thumb-instructions are used instead.

**ARM64**

**Non-optimizing GCC (Linaro) 4.9**

Listing 1.56: Non-optimizing GCC (Linaro) 4.9

```assembly
.LC2:
    .string "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d"

f3:
    ; grab more space in stack:
    sub   sp, sp, #32
    ; save FP and LR in stack frame:
    stp   x29, x30, [sp,16]
    ; set stack frame (FP=SP):
    add   x29, sp, 16
    adrp  x0, .LC2 ; "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d"
    add   x0, x0, :lo12:.LC2
    mov   w1, 8 ; 9th argument
    str   w1, [sp] ; store 9th argument in the stack
    mov   w1, 1
    mov   w2, 2
    mov   w3, 3
    mov   w4, 4
    mov   w5, 5
    mov   w6, 6
    mov   w7, 7
    bl    printf
    sub   sp, x29, #16
    ldp   x29, x30, [sp,16]
    add   sp, sp, #2
    ret
```

The first 8 arguments are passed in X- or W-registers: *(Procedure Call Standard for the ARM 64-bit Architecture (AArch64), (2013))*[^1]. A string pointer requires a 64-bit register, so it’s passed in X0. All other values have a `int` 32-bit type, so they are stored in the 32-bit part of the registers (W-). The 9th argument (8) is passed via the stack. Indeed: it’s not possible to pass large number of arguments through registers, because the number of registers is limited.

Optimizing GCC (Linaro) 4.9 generates the same code.

**1.11.3 MIPS**

3 arguments

**Optimizing GCC 4.4.5**

[^1]: Also available as [http://go.yurichev.com/17287](http://go.yurichev.com/17287)
The main difference with the “Hello, world!” example is that in this case printf() is called instead of puts() and 3 more arguments are passed through the registers $5...$7 (or $A0...A2). That is why these registers are prefixed with A-, which implies they are used for function arguments passing.

Listing 1.57: Optimizing GCC 4.4.5 (assembly output)

```assembly
$LCO:
.ascii "a=%d; b=%d; c=%d\000"
main:
    ; function prologue:
    lui $28, hi(__gnu_local_gp)
    addiu $sp, $sp, -32
    addiu $28, $28, lo(__gnu_local_gp)
    sw $31, 28($sp)
    ; load address of printf():

    ; call printf():
    jalr $25
    ; set 4th argument of printf() (branch delay slot):
    li $7, 3 # 0x3
    ; function epilogue:
    lw $31, 28($sp)
    ; set return value to 0:
    move $2, $0
    ; return
    j $31
addiu $sp, $sp, 32 ; branch delay slot
```

Listing 1.58: Optimizing GCC 4.4.5 (IDA)

```assembly
.text: 00000000 main:
.text: 00000000 var_10 = -0x10
.text: 00000000 var_4 = -4
.text: 00000000 ; function prologue:
.text: 00000000 lui $gp, (__gnu_local_gp >> 16)
.text: 00000004 addiu $sp, -0x20
.text: 00000008 la $gp, (__gnu_local_gp & 0xFFFF)
.text: 0000000c sw $ra, 0x20+var_4($sp)
.text: 00000010 sw $gp, 0x20+var_10($sp)
 ; load address of printf():
.text: 00000014 lw $t9, (printf & 0xFFFF)($gp)
 ; load address of the text string and set 1st argument of printf():
.text: 00000018 la $a0, $LCO # "a=%d; b=%d; c=%d"
 ; set 2nd argument of printf():
.text: 00000020 li $a1, 1
 ; set 3rd argument of printf():
.text: 00000024 li $a2, 2
 ; call printf():
.text: 00000028 jalr $t9
 ; set 4th argument of printf() (branch delay slot):
.text: 0000002c li $a3, 3
 ; function epilogue:
.text: 00000030 lw $ra, 0x20+var_4($sp)
 ; set return value to 0:
.text: 00000034 move $v0, $zero
 ; return
.text: 00000038 jr $ra
.text: 0000003c addiu $sp, 0x20 ; branch delay slot
```

IDA has coalesced pair of LUI and ADDIU instructions into one LA pseudo instruction. That’s why there are no instruction at address 0x1C: because LA occupies 8 bytes.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Non-optimizing GCC 4.4.5

Non-optimizing GCC is more verbose:

Listing 1.59: Non-optimizing GCC 4.4.5 (assembly output)

```
$LCO:
    .ascii "a=%d; b=%d; c=%d\000"

main:
    ; function prologue:
    addiu $sp,$sp,-32
    sw $31,28($sp)
    sw $fp,24($sp)
    move $fp,$sp
    lui $28,%hi(__gnu_local_gp)
    addiu $28,$28,%lo(__gnu_local_gp)
    ; load address of the text string:
    lui $2,%hi($LCO)
    addiu $2,$2,%lo($LCO)
    ; set 1st argument of printf():
    move $4,$2
    ; set 2nd argument of printf():
    li $5,1 # 0x1
    ; set 3rd argument of printf():
    li $6,2 # 0x2
    ; set 4th argument of printf():
    li $7,3 # 0x3
    ; get address of printf():
    lw $2,%call16(printf)($28)
    nop
    ; call printf():
    move $25,$2
    jalr $25
    nop
    ; function epilogue:
    lw $28,16($fp)
    ; set return value to 0:
    move $2,$0
    move $sp,$fp
    lw $31,28($sp)
    lw $fp,24($sp)
    addiu $sp,$sp,32
    ; return
    j $31
    nop
```

Listing 1.60: Non-optimizing GCC 4.4.5 (IDA)

```
.text:00000000  main:
.text:00000000
.text:00000000  var_10   = -0x10
.text:00000000  var_8     = -8
.text:00000000  var_4     = -4
.text:00000000
; function prologue:
.text:00000000  addiu $sp, -0x20
.text:00000004  sw $ra, 0x20+var_4($sp)
.text:00000008  sw $fp, 0x20+var_8($sp)
.text:0000000c  move $fp, $sp
.text:00000010  la $gp, __gnu_local_gp
.text:00000018  sw $gp, 0x20+var_10($sp)
; load address of the text string:

; set 2nd argument of printf():
.text:00000028  li $a1, 1
; set 3rd argument of printf():
.text:0000002c  li $a2, 2
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
8 arguments

Let’s use again the example with 9 arguments from the previous section: 1.11.1 on page 50.

```
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n", 1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
}
```

Optimizing GCC 4.4.5

Only the first 4 arguments are passed in the $A0 ...$A3 registers, the rest are passed via the stack.

This is the O32 calling convention (which is the most common one in the MIPS world). Other calling conventions (like N32) may use the registers for different purposes.

SW abbreviates “Store Word” (from register to memory). MIPS lacks instructions for storing a value into memory, so an instruction pair has to be used instead (LI/SW).

Listing 1.61: Optimizing GCC 4.4.5 (assembly output)

```
$LCO:

1.11.5 By the way

By the way, this difference between the arguments passing in x86, x64, fastcall, ARM and MIPS is a good illustration of the fact that the CPU is oblivious to how the arguments are passed to functions. It is also

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
possible to create a hypothetical compiler able to pass arguments via a special structure without using stack at all.

MIPS $A0 …$A3 registers are labeled this way only for convenience (that is in the O32 calling convention). Programmers may use any other register (well, maybe except $ZERO) to pass data or use any other calling convention.

The CPU is not aware of calling conventions whatsoever.

We may also recall how new coming assembly language programmers passing arguments into other functions: usually via registers, without any explicit order, or even via global variables. Of course, it works fine.

### 1.12 scanf()

Now let’s use scanf().

#### 1.12.1 Simple example

```c
#include <stdio.h>

int main()
{
    int x;
    printf (“Enter X:\n”);
    scanf (“%d”, &x);
    printf (“You entered %d...\n”, x);
    return 0;
}
```

It’s not clever to use scanf() for user interactions nowadays. But we can, however, illustrate passing a pointer to a variable of type int.

**About pointers**

Pointers are one of the fundamental concepts in computer science. Often, passing a large array, structure or object as an argument to another function is too expensive, while passing their address is much cheaper. For example, if you going to print a text string to console, it’s much easier to pass its address into OS kernel.

In addition if the callee function needs to modify something in the large array or structure received as a parameter and return back the entire structure then the situation is close to absurd. So the simplest thing to do is to pass the address of the array or structure to the callee function, and let it change what needs to be changed.

A pointer in C/C++—is simply an address of some memory location.

In x86, the address is represented as a 32-bit number (i.e., it occupies 4 bytes), while in x86-64 it is a 64-bit number (occupying 8 bytes). By the way, that is the reason behind some people’s indignation related to switching to x86-64—all pointers in the x64-architecture require twice as much space, including cache memory, which is “expensive” memory.

It is possible to work with untyped pointers only, given some effort; e.g. the standard C function memcpy(), that copies a block from one memory location to another, takes 2 pointers of type void* as arguments, since it is impossible to predict the type of the data you would like to copy. Data types are not important, only the block size matters.

Pointers are also widely used when a function needs to return more than one value (we are going to get back to this later (3.21 on page 603)).

**scanf()** function—is such a case.
Besides the fact that the function needs to indicate how many values were successfully read, it also needs to return all these values.

In C/C++ the pointer type is only needed for compile-time type checking.

Internally, in the compiled code there is no information about pointer types at all.

**x86**

**MSVC**

Here is what we get after compiling with MSVC 2010:

```assembly
CONST SEGMENT
SG3831 DB 'Enter X:', 0AH, 00H
SG3832 DB ' %d', 00H
SG3833 DB 'You entered %d...', 0AH, 00H
CONST ENDS
PUBLIC _main
EXTRN _scanf:PROC
EXTRN _printf:PROC
; Function compile flags: /Odtp
_TEXT SEGMENT
_x$ = -4 ; size = 4
_main PROC
    push ebp
    mov ebp, esp
    push ecx
    push OFFSET $SG3831 ; 'Enter X:'
    call _printf
    add esp, 4
    lea eax, DWORD PTR _x$[ebp]
    push eax
    push OFFSET $SG3832 ; '%d'
    call _scanf
    add esp, 8
    mov ecx, DWORD PTR _x$[ebp]
    push ecx
    push OFFSET $SG3833 ; 'You entered %d...'
    call _printf
    add esp, 8

; return 0
xor eax, eax
mov esp, ebp
pop ebp
ret 0
_main ENDP
_TEXT ENDS
```

_x$ is a local variable.

According to the C/C++ standard it must be visible only in this function and not from any other external scope. Traditionally, local variables are stored on the stack. There are probably other ways to allocate them, but in x86 that is the way it is.

The goal of the instruction following the function prologue, PUSH ECX, is not to save the ECX state (notice the absence of corresponding POP ECX at the function’s end).

In fact it allocates 4 bytes on the stack for storing the _x$ variable.

_x$ is to be accessed with the assistance of the __x$ macro (it equals to -4) and the EBP register pointing to the current frame.

Over the span of the function’s execution, EBP is pointing to the current stack frame making it possible to access local variables and function arguments via EBP+offset.

It is also possible to use ESP for the same purpose, although that is not very convenient since it changes frequently. The value of the EBP could be perceived as a frozen state of the value in ESP at the start of the function’s execution.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Here is a typical stack frame layout in 32-bit environment:

```
<table>
<thead>
<tr>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBP-8</td>
<td>local variable #2, marked in IDA as var_8</td>
</tr>
<tr>
<td>EBP-4</td>
<td>local variable #1, marked in IDA as var_4</td>
</tr>
<tr>
<td>EBP</td>
<td>saved value of EBP</td>
</tr>
<tr>
<td>EBP+4</td>
<td>return address</td>
</tr>
<tr>
<td>EBP+8</td>
<td>argument#1, marked in IDA as arg_0</td>
</tr>
<tr>
<td>EBP+0xC</td>
<td>argument#2, marked in IDA as arg_4</td>
</tr>
<tr>
<td>EBP+0x10</td>
<td>argument#3, marked in IDA as arg_8</td>
</tr>
</tbody>
</table>
```

The scanf() function in our example has two arguments.

The first one is a pointer to the string containing %d and the second is the address of the x variable.

First, the x variable’s address is loaded into the EAX register by the lea eax, DWORD PTR _x$[ebp] instruction.

LEA stands for load effective address, and is often used for forming an address (.1.6 on page 1001).

We could say that in this case LEA simply stores the sum of the EBP register value and the _x$ macro in the EAX register.

This is the same as lea eax, [ebp-4].

So, 4 is being subtracted from the EBP register value and the result is loaded in the EAX register. Next the EAX register value is pushed into the stack and scanf() is being called.

printf() is being called after that with its first argument — a pointer to the string: You entered %d...

The second argument is prepared with: mov ecx, [ebp-4]. The instruction stores the x variable value and not its address, in the ECX register.

Next the value in the ECX is stored on the stack and the last printf() is being called.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's try this example in OllyDbg. Let's load it and keep pressing F8 (step over) until we reach our executable file instead of ntdll.dll. Scroll up until main() appears.

Click on the first instruction (PUSH EBP), press F2 (set a breakpoint), then F9 (Run). The breakpoint will be triggered when main() begins.

Let's trace to the point where the address of the variable \( x \) is calculated:

---

**Figure 1.13: OllyDbg: The address of the local variable is calculated**

Right-click the EAX in the registers window and then select “Follow in stack”.

This address will appear in the stack window. The red arrow has been added, pointing to the variable in the local stack. At that moment this location contains some garbage (0x6E494714). Now with the help of PUSH instruction the address of this stack element is going to be stored to the same stack on the next position. Let's trace with F8 until the scanf() execution completes. During the scanf() execution, we input, for example, 123, in the console window:

Enter X: 123

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
scanf() completed its execution already:

Figure 1.14: OllyDbg: scanf() executed

scanf() returns 1 in EAX, which implies that it has read successfully one value. If we look again at the stack element corresponding to the local variable it now contains 0x7B (123).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Later this value is copied from the stack to the ECX register and passed to printf().

GCC

Let's try to compile this code in GCC 4.4.1 under Linux:

```
main proc near

var_20 = dword ptr -20h
var_1C = dword ptr -1Ch
var_4  = dword ptr -4

push   ebp
mov    ebp, esp
and    esp, 0FFFFFF0h
sub    esp, 20h
mov    [esp+20h+var_20], offset aEnterX ;"Enter X:"
call   _puts
mov    eax, offset aD ;"%d"
lea    edx, [esp+20h+var_4]
mov    [esp+20h+var_1C], edx
mov    [esp+20h+var_20], eax
call   __isoc99_scanf
mov    edx, [esp+20h+var_4]
mov    eax, offset aYouEnteredD___ ;"You entered %d...\n"
mov    [esp+20h+var_1C], edx
mov    [esp+20h+var_20], eax
call   printf
mov    eax, 0
leave
ret

main
endp
```

GCC replaced the printf() call with call to puts(). The reason for this was explained in (1.5.3 on page 20).

As in the MSVC example—the arguments are placed on the stack using the MOV instruction.

By the way

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This simple example is a demonstration of the fact that compiler translates list of expressions in C/C++
block into sequential list of instructions. There are nothing between expressions in C/C++, and so in
resulting machine code, there are nothing between, control flow slips from one expression to the next one.

x64

The picture here is similar with the difference that the registers, rather than the stack, are used for arguments passing.

MSVC

Listing 1.71: MSVC 2012 x64

```c

In order for scanf() to be able to read item it needs a parameter—pointer to an int. int is 32-bit, so we need 4 bytes to store it somewhere in memory, and it fits exactly in a 32-bit register. A place for the local variable x is allocated in the stack and IDA has named it var_8. It is not necessary, however, to allocate a such since SP (stack pointer) is already pointing to that space and it can be used directly.

So, SP's value is copied to the R1 register and, together with the format-string, passed to scanf().

PUSH/POP instructions behaves differently in ARM than in x86 (it's the other way around). They are synonyms to STM/STMDB/LDM/LDMIA instructions. And PUSH instruction first writes a value into the stack, and then subtracts SP by 4. POP first adds 4 to SP, and then reads a value from the stack. Hence, after PUSH, SP points to an unused space in stack. It is used by scanf(), and by printf() after.

LDMIA means Load Multiple Registers Increment address After each transfer. STMDB means Store Multiple Registers Decrement address Before each transfer.

Later, with the help of the LDR instruction, this value is moved from the stack to the R1 register in order to be passed to printf().

ARM64

Listing 1.73: Non-optimizing GCC 4.9.1 ARM64

.LC0:     .string "Enter X:"

; load pointer to the "Enter X:" string:
        adrp  x0, .LC0
        add  x0, x0, :lo12:.LC0
X0=pointer to the "Enter X:" string
; print it:
        bl    puts
; load pointer to the "%d" string:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There is 32 bytes are allocated for stack frame, which is bigger than it needed. Perhaps some memory aligning issue? The most interesting part is finding space for the x variable in the stack frame (line 22). Why 28? Somehow, compiler decided to place this variable at the end of stack frame instead of beginning. The address is passed to scanf(), which just stores the user input value in the memory at that address. This is 32-bit value of type int. The value is fetched at line 27 and then passed to printf().

MIPS

A place in the local stack is allocated for the x variable, and it is to be referred as $sp+24. Its address is passed to scanf(), and the user input values is loaded using the LW ("Load Word") instruction and then passed to printf().

Listing 1.74: Optimizing GCC 4.4.5 (assembly output)

$LC0:  .asci "Enter X:\000"
$LC1:  .asci "%d\000"
$LC2:  .asci "You entered %d...\012\000"

  lw $25, %call16(printf)($28)
  lui $4,%hi($LC2)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
1.12.2 The classic mistake

It’s a very popular mistake (and/or typo) to pass a value of x instead of pointer to x:

```c
#include <stdio.h>

int main()
{
    int x;
    printf ("Enter X:\n");
    return 0;

    // Incorrectly passing a value instead of pointer
    scanf ("%d", &x);
    printf ("You entered %d...\n", x);
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
scanf("%d", x); // BUG
printf("You entered %d...\n", x);
return 0;
}
```

So what happens here? `x` is not initialized and contains some random noise from local stack. When `scanf()` called, it takes string from user, parses it into number and tries to write it into `x`, treating it as an address in memory. But there is a random noise, so `scanf()` will try to write at random address. Most likely, the process will crash.

Interestingly enough, some CRT libraries in debug build, put visually distinctive patterns into memory just allocated, like 0xCCCCCCCC or 0x0BADF00D and so on. In this case, `x` may contain 0xCCCCCCCC, and `scanf()` would try to write at address 0xCCCCCCCC. And if you’ll notice that something in your process tries to write at address 0xCCCCCCCC, you’ll know that uninitialized variable (or pointer) gets used without prior initialization. This is better than as if newly allocated memory is just cleared by zero bytes.

### 1.12.3 Global variables

What if the `x` variable from the previous example isn’t local but a global one? Then it would have been accessible from any point, not only from the function body. Global variables are considered anti-pattern, but for the sake of the experiment, we could do this.

```c
#include <stdio.h>

// now x is global variable
int x;

int main()
{
    printf("Enter X:\n");
    scanf("%d", &x);
    printf("You entered %d...\n", x);
    return 0;
}
```

**MSVC: x86**

```
_DATA SEGMENT
COMM _x:DWORD
$SG2456  DB  'Enter X: ', 0AH, 00H
$SG2457  DB  '%d', 00H
$SG2458  DB  'You entered %d...', 0AH, 00H
_DATA ENDS
PUBLIC _main
EXTRN __scanf:PROC
EXTRN __printf:PROC
; Function compile flags: /Odtp
_TEXT SEGMENT
_main PROC
    push ebp
    mov ebp, esp
    push OFFSET $SG2456
    call __printf
    add esp, 4
    push OFFSET _x
    push OFFSET $SG2457
    call __scanf
    add esp, 8
    mov eax, DWORD PTR _x
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
In this case the x variable is defined in the _DATA segment and no memory is allocated in the local stack. It is accessed directly, not through the stack. Uninitialized global variables take no space in the executable file (indeed, why one needs to allocate space for variables initially set to zero?), but when someone accesses their address, the OS will allocate a block of zeros there.

Now let's explicitly assign a value to the variable:

```c
int x=10; // default value
```

We got:

```c
_DATA SEGMENT
_x DD 0aH
...
```

Here we see a value 0xA of DWORD type (DD stands for DWORD = 32 bit) for this variable.

If you open the compiled .exe in IDA, you can see the x variable placed at the beginning of the _DATA segment, and after it you can see text strings.

If you open the compiled .exe from the previous example in IDA, where the value of x hasn’t been set, you would see something like this:

Listing 1.76: IDA

```

x is marked with ? with the rest of the variables that do not need to be initialized. This implies that after loading the .exe to the memory, a space for all these variables is to be allocated and filled with zeros [ISO/IEC 9899:TC3 (C C99 standard), (2007)6.7.8p10]. But in the .exe file these uninitialized variables do not occupy anything. This is convenient for large arrays, for example.

---

73 That is how a VM behaves

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Things are even simpler here:

The variable is located in the data segment. After the PUSH instruction (pushing the address of x) gets executed, the address appears in the stack window. Right-click on that row and select “Follow in dump”. The variable will appear in the memory window on the left. After we have entered 123 in the console, 0x7B appears in the memory window (see the highlighted screenshot regions).

But why is the first byte 7B? Thinking logically, 00 00 00 7B must be there. The cause for this is referred as endianness, and x86 uses little-endian. This implies that the lowest byte is written first, and the highest written last. Read more about it at: 2.8 on page 469. Back to the example, the 32-bit value is loaded from this memory address into EAX and passed to printf().

The memory address of x is 0x00C53394.
In OllyDbg we can review the process memory map (Alt-M) and we can see that this address is inside the .data PE-segment of our program:

![OllyDbg: process memory map](image)

**Figure 1.17: OllyDbg: process memory map**

**GCC: x86**

The picture in Linux is near the same, with the difference that the uninitialized variables are located in the _bss segment. In **ELF** file this segment has the following attributes:

```
; Segment type: Uninitialized
; Segment permissions: Read/Write
```

If you, however, initialize the variable with some value e.g. 10, it is to be placed in the _data segment, which has the following attributes:

```
; Segment type: Pure data
; Segment permissions: Read/Write
```

**MSVC: x64**

```
.DATA SEGMENT
COMM x:DWORD
$SG2924 DB 'Enter X: ', 0AH, 00H
$SG2925 DB '°d°', 00H
$SG2926 DB 'You entered °d...°', 0AH, 00H
_DATA ENDS
```

---

*[1] Executable File format widely used in *NIX systems including Linux

(For statistics collecting purposes) if you've read this far, please click [here](link). Thanks!
The code is almost the same as in x86. Please note that the address of the $x$ variable is passed to \texttt{scanf()} using a \texttt{LEA} instruction, while the variable's value is passed to the second \texttt{printf()} using a \texttt{MOV} instruction. \texttt{DWORD PTR}—is a part of the assembly language (no relation to the machine code), indicating that the variable data size is 32-bit and the \texttt{MOV} instruction has to be encoded accordingly.

**ARM: Optimizing Keil 6/2013 (Thumb mode)**

Listing 1.78: IDA

(For statistics collecting purposes) if you've read this far, please click \texttt{here}. Thanks!
So, the x variable is now global and for this reason located in another segment, namely the data segment (.data). One could ask, why are the text strings located in the code segment (.text) and x is located right here? Because it is a variable and by definition its value could change. Moreover it could possibly change often. While text strings has constant type, they will not be changed, so they are located in the .text segment.

The code segment might sometimes be located in a ROM\textsuperscript{75} chip (keep in mind, we now deal with embedded microelectronics, and memory scarcity is common here), and changeable variables — in RAM.

It is not very economical to store constant variables in RAM when you have ROM.

Furthermore, constant variables in RAM must be initialized, because after powering on, the RAM, obviously, contains random information.

Moving forward, we see a pointer to the x (off_2C) variable in the code segment, and that all operations with the variable occur via this pointer.

That is because the x variable could be located somewhere far from this particular code fragment, so its address must be saved somewhere in close proximity to the code.

The LDR instruction in Thumb mode can only address variables in a range of 1020 bytes from its location, and in ARM-mode — variables in range of ±4095 bytes.

And so the address of the x variable must be located somewhere in close proximity, because there is no guarantee that the linker would be able to accommodate the variable somewhere nearby the code, it may well be even in an external memory chip!

One more thing: if a variable is declared as \texttt{const}, the Keil compiler allocates it in the .constdata segment. Perhaps thereafter, the linker could place this segment in ROM too, along with the code segment.

\textbf{ARM64}

\begin{verbatim}
1 .comm  x,4,4
2 .LC0: .string "Enter X:"
3 .LC1: .string "%d"
4 .LC2: .string "You entered %d...\n"
5 f5:
6 ; save FP and LR in stack frame:
7        stp   x29, x30, [sp, -16]!
8 ; set stack frame (FP=SP)
9        add   x29, sp, 0
10 ; load pointer to the "Enter X:" string:
11        adrp  x0, .LC0
12        add   x0, x0, :lo12:.LC0
13        bl     puts
14 ; load pointer to the "%d" string:
15        adrp  x0, .LC1
16        add   x0, x0, :lo12:.LC1
17 ; form address of x global variable:
18        adrp  x1, x
19        add   x1, x1, :lo12:x
20        bl     __isoc99_scanf
21 ; form address of x global variable again:
22        adrp  x0, x
23        add   x0, x0, :lo12:x
24 ; load value from memory at this address:
25        ldr   w1, [x0]
26 ; load pointer to the "You entered %d...\n" string:
27        adrp  x0, .LC2
28        add   x0, x0, :lo12:.LC2
29        bl     printf
30 ; return 0
31        mov   w0, 0
\end{verbatim}

\textsuperscript{75}Read-Only Memory

(For statistics collecting purposes) if you’ve read this far, please click \url{here}. Thanks!
In this case the \( x \) variable is declared as global and its address is calculated using the ADRP/ADD instruction pair (lines 21 and 25).

**MIPS**

**Uninitialized global variable**

So now the \( x \) variable is global. Let’s compile to executable file rather than object file and load it into IDA. IDA displays the \( x \) variable in the .sbss ELF section (remember the “Global Pointer”? 1.5.4 on page 24), since the variable is not initialized at the start.

Listing 1.80: Optimizing GCC 4.4.5 (IDA)

.IDA reduces the amount of information, so we’ll also do a listing using objdump and comment it:

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Now we see the $x$ variable address is read from a 64KiB data buffer using GP and adding negative offset to it (line 18). More than that, the addresses of the three external functions which are used in our example (puts(), scanf(), printf()), are also read from the 64KiB global data buffer using GP (lines 9, 16 and 26). GP points to the middle of the buffer, and such offset suggests that all three function’s addresses, and also the address of the $x$ variable, are all stored somewhere at the beginning of that buffer. That make sense, because our example is tiny.

Another thing worth mentioning is that the function ends with two NOPs (MOVE $AT,$AT — an idle instruction), in order to align next function’s start on 16-byte boundary.

**Initialized global variable**

Let’s alter our example by giving the $x$ variable a default value:

```c
int x=10; // default value
```

Now IDA shows that the $x$ variable is residing in the .data section:

```asm
.text:004006A0 main:
.text:004006A0 var_10  = -0x10
.text:004006A0 var_8   = -8
.text:004006A0 var_4   = -4
.text:004006A0
.text:004006A0 lui     $gp, 0x42
.text:004006A4 addiu   $sp, -0x20
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Why not .sdata? Perhaps that this depends on some GCC option?

The variable's address must be formed using a pair of instructions.

In our case those are

```
.globl x
.word 0xA
```

Why not .sdata? Perhaps that this depends on some GCC option?

Nevertheless, now x is in .data, which is a general memory area, and we can take a look how to work with variables there.

The variable's address must be formed using a pair of instructions.

In our case those are LUI (“Load Upper Immediate”) and ADDIU (“Add Immediate Unsigned Word”).

Here is also the objdump listing for close inspection:

```
Listing 1.83: Optimizing GCC 4.4.5 (objdump)
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
We see that the address is formed using LUI and ADDIU, but the high part of address is still in the S0 register, and it is possible to encode the offset in a LW ("Load Word") instruction, so one single LW is enough to load a value from the variable and pass it to printf().

Registers holding temporary data are prefixed with T-, but here we also see some prefixed with S-, the contents of which must be preserved before use in other functions (i.e., saved somewhere).

That is why the value of S0 has been set at address 0x4006cc and has been used again at address 0x4006e8, after the scanf() call. The scanf() function does not change its value.

## 1.12.4 scanf()

As was noted before, it is slightly old-fashioned to use scanf() today. But if we have to, we have to check if scanf() finishes correctly without an error.

```c
#include <stdio.h>

int main()
{
    int x;
    printf("Enter X:\n");
    if (scanf("%d", &x)==1)
        printf("You entered %d...\n", x);
    else
        printf("What you entered? Huh?\n");
    return 0;
}
```

By standard, the scanf() function returns the number of fields it has successfully read. In our case, if everything goes fine and the user enters a number scanf() returns 1, or in case of error (or EOF) — 0.

Let's add some C code to check the scanf() return value and print error message in case of an error. This works as expected:

```
C:\...>ex3.exe
Enter X:
123
You entered 123...
C:\...>ex3.exe
Enter X:
ouch
What you entered? Huh?
```

---

76 scanf, wscanf: [MSDN](https://docs.microsoft.com/en-us/windows/win32/crt/scanf)

77 End of File
Here is what we get in the assembly output (MSVC 2010):

```assembly
lea    eax, DWORD PTR _x$[ebp]
push   eax
push   OFFSET $SG3833 ; '%d', 00H
call   _scanf
add    esp, 8
cmp    eax, 1
jne    SHORT $LN2@main
mov    ecx, DWORD PTR _x$[ebp]
push   ecx
push   OFFSET $SG3834 ; 'You entered %d...', 0AH, 00H
call   _printf
add    esp, 8
jmp    SHORT $LN1@main
$LN2@main:
push   OFFSET $SG3836 ; 'What you entered? Huh?', 0AH, 00H
call   _printf
add    esp, 4
$LN1@main:
xor    eax, eax
```

The **caller** function (main()) needs the **callee** function (scanf()) result, so the **callee** returns it in the EAX register.

We check it with the help of the instruction CMP EAX, 1 (**CoMPare**). In other words, we compare the value in the EAX register with 1.

A JNE conditional jump follows the CMP instruction. JNE stands for **Jump if Not Equal**.

So, if the value in the EAX register is not equal to 1, the CPU will pass the execution to the address mentioned in the JNE operand, in our case $LN2@main. Passing the control to this address results in the CPU executing printf() with the argument What you entered? Huh?. But if everything is fine, the conditional jump is not be taken, and another printf() call is to be executed, with two arguments: ‘You entered %d...’ and the value of x.

Since in this case the second printf() has not to be executed, there is a JMP preceding it (unconditional jump). It passes the control to the point after the second printf() and just before the XOR EAX, EAX instruction, which implements return 0.

So, it could be said that comparing a value with another is **usually** implemented by CMP/Jcc instruction pair, where cc is condition code. CMP compares two values and sets processor flags78. Jcc checks those flags and decides to either pass the control to the specified address or not.

This could sound paradoxical, but the CMP instruction is in fact SUB (subtract). All arithmetic instructions set processor flags, not just CMP. If we compare 1 and 1, 1−1 is 0 so the ZF flag would be set (meaning that the last result is 0). In no other circumstances ZF can be set, except when the operands are equal. JNE checks only the ZF flag and jumps only if it is not set. JNE is in fact a synonym for JNZ (jump if not zero). Assembler translates both JNE and JNZ instructions into the same opcode. So, the CMP instruction can be replaced with a SUB instruction and almost everything will be fine, with the difference that SUB alters the value of the first operand. CMP is **SUB without saving the result, but affecting flags**.

**MSVC: x86: IDA**

It is time to run **IDA** and try to do something in it. By the way, for beginners it is good idea to use /MD option in MSVC, which means that all these standard functions are not be linked with the executable file, but are to be imported from the MSVCR*.DLL file instead. Thus it will be easier to see which standard function are used and where.

While analyzing code in **IDA**, it is very helpful to leave notes for oneself (and others). In instance, analyzing this example, we see that JNZ is to be triggered in case of an error. So it is possible to move the cursor to the label, press “n” and rename it to “error”. Create another label—into “exit”. Here is my result:

```
.text:00401000   _main proc near
.text:00401000
```

78x86 flags, see also: wikipedia.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now it is slightly easier to understand the code. However, it is not a good idea to comment on every instruction.

You could also hide(collapse) parts of a function in IDA. To do that mark the block, then press “–” on the numerical pad and enter the text to be displayed instead.

Let’s hide two blocks and give them names:

```
.text:00401000 _text segment para public 'CODE' use32
.text:00401000 ; ask for X
.text:00401024 ; get X
.text:00401027 ; print result
.text:0040103B ; short exit
.text:0040103D error: ; CODE XREF: _main+27
.text:0040103D ; short error
.text:00401042 ; short exit
.text:00401048 ; short exit
.text:0040104B ; short exit
.text:0040104B exit: ; CODE XREF: _main+3B
.text:0040104B ; print error
.text:00401050 ret
```

To expand previously collapsed parts of the code, use “+” on the numerical pad.
By pressing “space”, we can see how IDA represents a function as a graph:

```
; int cdecl main()
_main proc near

var_4= dword ptr -4
argc= dword ptr 8
argv= dword ptr 0Ch
envp= dword ptr 10h
push ebp
mov ebp, esp
push ecx
push offset Format ; "Enter X:\n"
call ds:printf
add esp, 4
lea eax, [ebp+var_4]
push eax
push offset a0 ; "\d"
call ds:scanf
add esp, 8
cmp eax, 1
jnz short error

mov ecx, [ebp+var_4]
push ecx
push offset aYou ; "You entered %d...\n"
call ds:printf
add esp, 8
jmp short exit

exit:
xor eax, eax
mov esp, ebp
pop ebp
ret
_main endp
```

Figure 1.18: Graph mode in IDA

There are two arrows after each conditional jump: green and red. The green arrow points to the block which executes if the jump is triggered, and red if otherwise.
It is possible to fold nodes in this mode and give them names as well ("group nodes"). Let’s do it for 3 blocks:

```c
; int __cdecl main()
_main proc near

var_4= dword ptr -4
argc= dword ptr 8
argv= dword ptr 0Ch
envp= dword ptr 10h

push ebp
mov ebp, esp
push ecx
push offset Format  ; "Enter X:\n"
call ds:printf
add esp, 4
lea eax, [ebp+var_4]
push eax
push offset aD  ; "%d"
call ds:scanf
add esp, 8
cmp eax, 1
jnz short error
```

That is very useful. It could be said that a very important part of the reverse engineers’ job (and any other researcher as well) is to reduce the amount of information they deal with.
Let's try to hack our program in OllyDbg, forcing it to think `scanf()` always works without error. When an address of a local variable is passed into `scanf()`, the variable initially contains some random garbage, in this case 0x6E494714:

![Figure 1.20: OllyDbg: passing variable address into `scanf()`](image)

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
While `scanf()` executes, in the console we enter something that is definitely not a number, like “asdasd”. `scanf()` finishes with 0 in EAX, which indicates that an error has occurred:

![Figure 1.21: OllyDbg: scanf() returning error](image)

We can also check the local variable in the stack and note that it has not changed. Indeed, what would `scanf()` write there? It simply did nothing except returning zero.

Let’s try to “hack” our program. Right-click on EAX, Among the options there is “Set to 1”. This is what we need.

We now have 1 in EAX, so the following check is to be executed as intended, and `printf()` will print the value of the variable in the stack.

When we run the program (F9) we can see the following in the console window:

```
Listing 1.84: console window

Enter X:
asdasd
You entered 1850296084...
```

Indeed, 1850296084 is a decimal representation of the number in the stack (0x6E494714)!

(For statistics collecting purposes) if you’ve read this far, please click [here](link). Thanks!
This can also be used as a simple example of executable file patching. We may try to patch the executable so the program would always print the input, no matter what we enter.

Assuming that the executable is compiled against external MSVCR*.DLL (i.e., with /MD option) \(^79\), we see the main() function at the beginning of the .text section. Let’s open the executable in Hiew and find the beginning of the .text section (Enter, F8, F6, Enter, Enter).

We can see this:

![Hiew: main() function](image)

Hiew finds ASCII \(^80\) strings and displays them, as it does with the imported functions’ names.

\(^79\)that’s what also called “dynamic linking”  
\(^80\)ASCII Zero (null-terminated ASCII string)
Move the cursor to address .00401027 (where the JNZ instruction, we have to bypass, is located), press F3, and then type “9090” (meaning two NOPs):

![Figure 1.23: Hiew: replacing JNZ with two NOPs](image)

Then press F9 (update). Now the executable is saved to the disk. It will behave as we wanted.

Two NOPs are probably not the most æsthetic approach. Another way to patch this instruction is to write just 0 to the second opcode byte (jump offset), so that JNZ will always jump to the next instruction.

We could also do the opposite: replace first byte with EB while not touching the second byte (jump offset). We would get an unconditional jump that is always triggered. In this case the error message would be printed every time, no matter the input.

**MSVC: x64**

Since we work here with int-typed variables, which are still 32-bit in x86-64, we see how the 32-bit part of the registers (prefixed with E-) are used here as well. While working with pointers, however, 64-bit register parts are used, prefixed with R-.

Listing 1.85: MSVC 2012 x64

```

ARM

ARM: Optimizing Keil 6/2013 (Thumb mode)

Listing 1.86: Optimizing Keil 6/2013 (Thumb mode)

var_8  = -8

    PUSH   {R3,LR}
    ADR    R0, aEnterX     ; "Enter X:\n"
    BL     __2printf
    MOV    R1, SP
    ADR    R0, aD         ; "%d"
    BL     __0scanf
    CMP    R0, #1
    BEQ    loc_1E
    BEQ    loc_1E
    ADR    R0, aWhatYouEntered ; "What you entered? Huh?\n"
    BL     __2printf
    loc_1A
    MOVS   R0, #0
    POP    {R3,PC}

loc_1E
    LDR    R1, [SP,#8+var_8]
    ADR    R0, aYouEnteredD___ ; "You entered %d...\n"
    BL     __2printf
    B loc_1A

The new instructions here are CMP and BEQ\(^1\).

CMP is analogous to the x86 instruction with the same name, it subtracts one of the arguments from the other and updates the conditional flags if needed.

\(^1\)(PowerPC, ARM) Branch if Equal

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
BEQ jumps to another address if the operands were equal to each other, or, if the result of the last computation has been 0, or if the Z flag is 1. It behaves as JZ in x86.

Everything else is simple: the execution flow forks in two branches, then the branches converge at the point where 0 is written into the R0 as a function return value, and then the function ends.

**ARM64**

Listing 1.87: Non-optimizing GCC 4.9.1 ARM64

```
.LC0:
.string "Enter X:"
.LC1:
.string "%d"
.LC2:
.string "You entered %d...\n"
.LC3:
.string "What you entered? Huh?"
f6:
; save FP and LR in stack frame:
  stp  x29, x30, [sp, -32]!
; set stack frame (FP=SP)
  add  x29, sp, 0
; load pointer to the "Enter X:" string:
  adrp  x0, .LC0
  add  x0, x0, :lo12:.LC0
  bl  puts
; load pointer to the "%d" string:
  adrp  x0, .LC1
  add  x0, x0, :lo12:.LC1
; calculate address of x variable in the local stack
  add  x1, x29, 28
  bl  __isoc99_scanf
; scanf() returned result in W0.
; check it:
  cmp  w0, 1
; BNE is Branch if Not Equal
  bne .L2
; at this moment W0=1, meaning no error
; load x value from the local stack
  ldr  w1, [x29,28]
; load pointer to the "You entered %d...\n" string:
  adrp  x0, .LC2
  add  x0, x0, :lo12:.LC2
  bl  printf
; skip the code, which print the "What you entered? Huh?" string:
  b .L3
.L2:
; load pointer to the "What you entered? Huh?" string:
  adrp  x0, .LC3
  add  x0, x0, :lo12:.LC3
  bl  puts
.L3:
; return 0
  mov  w0, 0
; restore FP and LR:
  ldp  x29, x30, [sp], 32
  ret
```

Code flow in this case forks with the use of CMP/BNE (Branch if Not Equal) instructions pair.

**MIPS**

.scanf() returns the result of its work in register $V0. It is checked at address 0x004006E4 by comparing the values in $V0 with $V1 (1 has been stored in $V1 earlier, at 0x004006DC). BEQ stands for “Branch Equal”. If the two values are equal (i.e., success), the execution jumps to address 0x0040070C.

Exercise

As we can see, the JNE/JNZ instruction can be easily replaced by the JE/JZ and vice versa (or BNE by BEQ and vice versa). But then the basic blocks must also be swapped. Try to do this in some of the examples.

1.12.5 Exercise

• http://challenges.re/53

1.13 Worth noting: global vs. local variables

Now that you know that global variables are filling with zeroes by OS at start ( 1.12.3 on page 77, [ISO/IEC 9899:TC3 (C 99 standard), (2007)6.7.8p10]), but local variables are not ( 1.9.4 on page 37).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Sometimes, you have a global variable that you forgot to initialize and your program relies on the fact that it has zero at start. Then you edit a program and move the global variable into a function to make it local. It wouldn’t be zeroed at initialization anymore and this can result in nasty bugs.

### 1.14 Accessing passed arguments

Now we figured out that the caller function is passing arguments to the callee via the stack. But how does the callee access them?

```c
#include <stdio.h>

int f (int a, int b, int c)
{
    return a*b+c;
};

int main()
{
    printf ("%d\n", f(1, 2, 3));
    return 0;
};
```

#### 1.14.1 x86

**MSVC**

Here is what we get after compilation (MSVC 2010 Express):

```assembly
_TEXT SEGMENT
    _a$ = 8 ; size = 4
    _b$ = 12 ; size = 4
    _c$ = 16 ; size = 4
_f PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _a$[ebp]
    imul eax, DWORD PTR _b$[ebp]
    add eax, DWORD PTR _c$[ebp]
    pop ebp
    ret 0
_f ENDP

_main PROC
    push ebp
    mov ebp, esp
    push 3 ; 3rd argument
    push 2 ; 2nd argument
    push 1 ; 1st argument
    call _f
    add esp, 12
    push eax
    push OFFSET $SG2463 ; '%d', 0aH, 00H
    call _printf
    add esp, 8 ; return 0
    xor eax, eax
    push ebp
    ret 0
_main ENDP
```

What we see is that the main() function pushes 3 numbers onto the stack and calls f(int,int,int).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Argument access inside f() is organized with the help of macros like: 
\_a$ = 8, in the same way as local variables, but with positive offsets (addressed with plus). So, we are addressing the outer side of the stack frame by adding the \_a$ macro to the value in the EBP register.

Then the value of \_a is stored into EAX. After IMUL instruction execution, the value in EAX is a product of the value in EAX and the content of \_b.  

After that, ADD adds the value in \_c to EAX.  

The value in EAX does not need to be moved: it is already where it must be. On returning to caller, it takes the EAX value and uses it as an argument to printf().

**MSVC + OllyDbg**

Let’s illustrate this in OllyDbg. When we trace to the first instruction in f() that uses one of the arguments (first one), we see that EBP is pointing to the stack frame, which is marked with a red rectangle.  
The first element of the stack frame is the saved value of EBP, the second one is RA, the third is the first function argument, then the second and third ones. 

To access the first function argument, one needs to add exactly 8 (2 32-bit words) to EBP. OllyDbg is aware about this, so it has added comments to the stack elements like “RETURN from” and “Arg1 = ...”, etc.

N.B.: Function arguments are not members of the function’s stack frame, they are rather members of the stack frame of the caller function.

Hence, OllyDbg marked “Arg” elements as members of another stack frame.

**GCC**

Let’s compile the same in GCC 4.4.1 and see the results in IDA:

```
Listing 1.91: GCC 4.4.1

public f
f proc near
arg_0 = dword ptr 8
arg_4 = dword ptr 0Ch
arg_8 = dword ptr 10h
```

For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The result is almost the same with some minor differences discussed earlier. The stack pointer is not set back after the two function calls (f and printf), because the penultimate LEAVE (.1.6 on page 1001) instruction takes care of this at the end.

1.14.2 x64

The story is a bit different in x86-64. Function arguments (first 4 or first 6 of them) are passed in registers i.e. the callee reads them from registers instead of reading them from the stack.

MSVC

Optimizing MSVC:

Listing 1.92: Optimizing MSVC 2012 x64

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As we can see, the compact function `f()` takes all its arguments from the registers.
The LEA instruction here is used for addition, apparently the compiler considered it faster than `ADD`.
LEA is also used in the `main()` function to prepare the first and third `f()` arguments. The compiler must have decided that this would work faster than the usual way of loading values into a register using `MOV` instruction.

Let's take a look at the non-optimizing MSVC output:

```plaintext
Listing 1.93: MSVC 2012 x64

f proc near
; shadow space:
arg_0 = dword ptr 8
arg_8 = dword ptr 10h
arg_10 = dword ptr 18h

; ECX - 1st argument
; EDX - 2nd argument
; R8D - 3rd argument
imul ecx, edx
lea eax, DWORD PTR [r8+rcx]
ret 0
f endp

main proc near
sub rsp, 28h
mov r8d, 3 ; 3rd argument
mov edx, 2 ; 2nd argument
mov ecx, 1 ; 1st argument
call f
mov edx, eax
lea rcx, $SG2931 ; "%d\n"
call printf

; return 0
xor eax, eax
add rsp, 28h
retn
main endp
```

It looks somewhat puzzling because all 3 arguments from the registers are saved to the stack for some reason. This is called “shadow space” 82: every Win64 may (but is not required to) save all 4 register values there. This is done for two reasons: 1) it is too lavish to allocate a whole register (or even 4 registers) for an input argument, so it will be accessed via stack; 2) the debugger is always aware where to find the function arguments at a break 83.

So, some large functions can save their input arguments in the “shadows space” if they want to use them during execution, but some small functions (like ours) may not do this.

It is a caller responsibility to allocate “shadow space” in the stack.

82MSDN
83MSDN
Optimizing GCC generates more or less understandable code:

### Listing 1.94: Optimizing GCC 4.4.6 x64

```assembly
f:
  ; EDI - 1st argument
  ; ESI - 2nd argument
  ; EDX - 3rd argument
  imul  esi, edi
  lea  eax, [rdx+rsi]
  ret

main:
  sub  rsp, 8
  mov  edx, 3
  mov  esi, 2
  mov  edi, 1
  call  f
  mov  edi, OFFSET FLAT:.LC0 ; "%d\n"
  mov  esi, eax
  xor  eax, eax ; number of vector registers passed
  call  printf
  xor  eax, eax
  add  rsp, 8
  ret
```

Non-optimizing GCC:

### Listing 1.95: GCC 4.4.6 x64

```assembly
f:
  ; EDI - 1st argument
  ; ESI - 2nd argument
  ; EDX - 3rd argument
  push  rbp
  mov  rbp, rsp
  mov  DWORD PTR [rbp-4], edi
  mov  DWORD PTR [rbp-8], esi
  mov  DWORD PTR [rbp-12], edx
  imul  eax, DWORD PTR [rbp-4]
  add  eax, DWORD PTR [rbp-8]
  leave
  ret

main:
  push  rbp
  mov  rbp, rsp
  mov  edx, 3
  mov  esi, 2
  mov  edi, 1
  call  f
  mov  edx, OFFSET FLAT:.LC0 ; "%d\n"
  mov  esi, edx
  mov  rdi, rax
  mov  eax, 0 ; number of vector registers passed
  call  printf
  mov  eax, 0
  leave
  ret
```

There are no “shadow space” requirements in System V *NIX ([Michael Matz, Jan Hubicka, Andreas Jaeger, Mark Mitchell, System V Application Binary Interface. AMD64 Architecture Processor Supplement, (2013)](https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf)), but the callee may want to save its arguments somewhere in case of registers shortage.

---

(For statistics collecting purposes) if you’ve read this far, please click [here](https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf). Thanks!
GCC: uint64_t instead of int

Our example works with 32-bit int, that is why 32-bit register parts are used (prefixed by E-).

It can be altered slightly in order to use 64-bit values:

```
#include <stdio.h>
#include <stdint.h>

uint64_t f (uint64_t a, uint64_t b, uint64_t c)
{
    return a*b+c;
}

int main()
{
    printf ("%lld\n", f(0x1122334455667788,
                       0x1111111122222222,
                       0x3333333344444444));
    return 0;
}
```

Listing 1.96: Optimizing GCC 4.4.6 x64

```
f proc near
    imul    rsi, rdi
    lea    rax, [rdx+rsi]
    retn
f endp

main proc near
    sub    rsp, 8
    mov    rdx, 3333333344444444h ; 3rd argument
    mov    rsi, 1111111122222222h ; 2nd argument
    mov    rdi, 1122334455667788h ; 1st argument
    call    f
    mov    edi, offset format ; "%lld\n"
    mov    rsi, rax
    xor    eax, eax ; number of vector registers passed
    call    __2printf
    xor    eax, eax
    add    rsp, 8
    retn
main endp
```

The code is the same, but this time the full size registers (prefixed by R-) are used.

1.14.3 ARM

Non-optimizing Keil 6/2013 (ARM mode)

```
.text:000000A4 00 30 A0 E1  MOV   R3, R0
.text:000000A8 93 21 20 E0  MLA   R0, R3, R1, R2
.text:000000AC 1E FF 2F E1  BX    LR
...
.text:000000B0 main
.text:000000B0 10 40 2D E9  STMFD  SP!, {R4,LR}
.text:000000B4 03 20 A0 E3  MOV   R2, #3
.text:000000B8 02 10 A0 E3  MOV   R1, #2
.text:000000BC 01 00 A0 E3  MOV   R0, #1
.text:000000C0 F7 FF FF EB  BL    f
.text:000000C4 00 40 A0 E1  MOV   R4, R0
.text:000000C8 04 10 A0 E1  MOV   R1, R4
.text:000000CC 5A 0F 8F E2  ADR   R0, a0_0 ; "%d\n"
.text:000000D0 E3 18 00 EB  BL    2printf
.text:000000D4 00 00 A0 E3  MOV   R0, #0
.text:000000D8 10 80 BD E8  LDMFD  SP!, {R4,PC}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The main() function simply calls two other functions, with three values passed to the first one — \( f() \).

As was noted before, in ARM the first 4 values are usually passed in the first 4 registers (R0-R3).

The \( f() \) function, as it seems, uses the first 3 registers (R0-R2) as arguments.

The MLA (Multiply Accumulate) instruction multiplies its first two operands (R3 and R1), adds the third operand (R2) to the product and stores the result into the zeroth register (R0), via which, by standard, functions return values.

Multiplication and addition at once (Fused multiply–add) is a very useful operation. By the way, there was no such instruction in x86 before FMA-instructions appeared in SIMD \(^{85}\).

The very first MOV R3, R0 instruction is, apparently, redundant (a single MLA instruction could be used here instead). The compiler has not optimized it, since this is non-optimizing compilation.

The BX instruction returns the control to the address stored in the LR register and, if necessary, switches the processor mode from Thumb to ARM or vice versa. This can be necessary since, as we can see, function \( f() \) is not aware from what kind of code it may be called, ARM or Thumb. Thus, if it gets called from Thumb code, BX is not only returns control to the calling function, but also switches the processor mode to Thumb. Or not switch, if the function has been called from ARM code [ARM(R) Architecture Reference Manual, ARMv7-A and ARMv7-R edition, (2012)A2.3.2].

### Optimizing Keil 6/2013 (ARM mode)

```
.text:00000098     f
.text:00000098 91 20 20 E0   MLA   R0, R1, R0, R2
.text:0000009C 1E FF 2F E1   BX   LR
```

And here is the \( f() \) function compiled by the Keil compiler in full optimization mode (-O3).

The MOV instruction was optimized out (or reduced) and now MLA uses all input registers and also places the result right into R0, exactly where the calling function will read and use it.

### Optimizing Keil 6/2013 (Thumb mode)

```
.text:0000005E 48 43   MULS   R0, R1
.text:00000060 80 18   ADDS   R0, R0, R2
.text:00000062 70 47   BX   LR
```

The MLA instruction is not available in Thumb mode, so the compiler generates the code doing these two operations (multiplication and addition) separately.

First the MULS instruction multiplies R0 by R1, leaving the result in register R0. The second instruction (ADDS) adds the result and R2 leaving the result in register R0.

### ARM64

### Optimizing GCC (Linaro) 4.9

Everything here is simple. MADD is just an instruction doing fused multiply/add (similar to the MLA we already saw). All 3 arguments are passed in the 32-bit parts of X-registers. Indeed, the argument types are 32-bit int's. The result is returned in W0.

Listing 1.97: Optimizing GCC (Linaro) 4.9

```
f:
   madd     w0, w0, w1, w2
   ret

main:
   ; save FP and LR to stack frame:
   stp     x29, x30, [sp, -16]!
   mov     w2, 3
```

\(^{85}\) wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
mov w1, 2
add x29, sp, 0
mov w0, 1
bl f
mov w1, w0
adrp x0, .LC7
add x0, x0, :lo12:.LC7
bl printf
; return 0
mov w0, 0
; restore FP and LR
ldp x29, x30, [sp], 16
ret

.LC7:
.string "\%d\n"

Let's also extend all data types to 64-bit uint64_t and test:

```
#include <stdio.h>
#include <stdint.h>

uint64_t f(uint64_t a, uint64_t b, uint64_t c)
{
    return a*b+c;
};

int main()
{
    printf ("%lld\n", f(0x122345567788, 0x1111111222222222, 0x3333334444444444));
    return 0;
};
```

```
f:
    madd x0, x0, x1, x2
    ret
main:
    mov x1, 13396
    adrp x0, .LC8
    stp x29, x30, [sp, -16]!
    movk x1, 0x27d0, lsl 16
    add x0, x0, :lo12:.LC8
    movk x1, 0x122, lsl 32
    add x29, sp, 0
    movk x1, 0x58be, lsl 48
    bl printf
    mov w0, 0
    ldp x29, x30, [sp], 16
    ret

.LC8:
    .string "%lld\n"
```

The f() function is the same, only the whole 64-bit X-registers are now used. Long 64-bit values are loaded into the registers by parts, this is also described here: 1.39.3 on page 445.

**Non-optimizing GCC (Linaro) 4.9**

The non-optimizing compiler is more redundant:

```
f:
    sub sp, sp, #16
    str w0, [sp,12]
    str w1, [sp,8]
    str w2, [sp,4]
```
The code saves its input arguments in the local stack, in case someone (or something) in this function needs using the W0...W2 registers. This prevents overwriting the original function arguments, which may be needed again in the future.

This is called Register Save Area. ([Procedure Call Standard for the ARM 64-bit Architecture (AArch64), (2013)](http://go.yurichev.com/17287)). The callee, however, is not obliged to save them. This is somewhat similar to “Shadow Space”: 1.14.2 on page 100.

Why did the optimizing GCC 4.9 drop this argument saving code? Because it did some additional optimizing work and concluded that the function arguments will not be needed in the future and also that the registers W0...W2 will not be used.

We also see a MUL/ADD instruction pair instead of single a MADD.

1.14.4 MIPS

Listing 1.98: Optimizing GCC 4.4.5

The first four function arguments are passed in four registers prefixed by A-.

---

86Also available as [http://go.yurichev.com/17287](http://go.yurichev.com/17287)
There are two special registers in MIPS: HI and LO which are filled with the 64-bit result of the multiplication during the execution of the MULT instruction.

These registers are accessible only by using the MFL0 and MFHI instructions. MFL0 here takes the low-part of the multiplication result and stores it into $V0. So the high 32-bit part of the multiplication result is dropped (the HI register content is not used). Indeed: we work with 32-bit int data types here.

Finally, ADDU (“Add Unsigned”) adds the value of the third argument to the result.

There are two different addition instructions in MIPS: ADD and ADDU. The difference between them is not related to signedness, but to exceptions. ADD can raise an exception on overflow, which is sometimes useful and supported in Ada PL, for instance. ADDU does not raise exceptions on overflow.

Since C/C++ does not support this, in our example we see ADDU instead of ADD.

The 32-bit result is left in $V0.

There is a new instruction for us in main(): JAL (“Jump and Link”).

The difference between JAL and JALR is that a relative offset is encoded in the first instruction, while JALR jumps to the absolute address stored in a register (“Jump and Link Register”).

Both f() and main() functions are located in the same object file, so the relative address of f() is known and fixed.

### 1.15 More about results returning

In x86, the result of function execution is usually returned in the EAX register. If it is byte type or a character (char), then the lowest part of register EAX (AL) is used. If a function returns a float number, the FPU register ST(0) is used instead. In ARM, the result is usually returned in the R0 register.

#### 1.15.1 Attempt to use the result of a function returning void

So, what if the main() function return value was declared of type void and not int? The so-called startup-code is calling main() roughly as follows:

```assembly
push envp
push argv
push argc
call main
push eax
call exit
```

In other words:

```c
exit(main(argc,argv,envp));
```

If you declare main() as void, nothing is to be returned explicitly (using the return statement), then something random, that has been stored in the EAX register at the end of main() becomes the sole argument of the exit() function. Most likely, there will be a random value, left from your function execution, so the exit code of program is pseudorandom.

We can illustrate this fact. Please note that here the main() function has a void return type:

```c
#include <stdio.h>

void main()
{
    printf ("Hello, world!\n");
}
```

Let's compile it in Linux.

87http://go.yurichev.com/17326
88See also: MSDN: Return Values (C++): MSDN

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
GCC 4.8.1 replaced `printf()` with `puts()` (we have seen this before: 1.5.3 on page 20), but that’s OK, since `puts()` returns the number of characters printed out, just like `printf()`. Please notice that EAX is not zeroed before `main()`’s end.

This implies that the value of EAX at the end of `main()` contains what `puts()` has left there.

```
.LC0:
    .string "Hello, world!"
main:
    push   ebp
    mov    ebp, esp
    and    esp, -16
    sub    esp, 16
    mov    DWORD PTR [esp], OFFSET FLAT:.LC0
    call   puts
    leave
    ret
```

Let’s write a bash script that shows the exit status:

```
#!/bin/sh
./hello_world
echo $?
```

And run it:

```
$ tst.sh
Hello, world!
14
```

14 is the number of characters printed. The number of characters printed *slips* from `printf()` through EAX/RAX into “exit code”.

Another example in the book: 3.29 on page 644.

By the way, when we decompile C++ in Hex-Rays, we can often encounter a function which terminated with destructor of some class:

```
... 
call ??1CString@@QAE@XZ ; CString:: CString(void)
mov    ecx, [esp+30h+var_C]
pop    edi
pop    ebx
mov    large fs:0, ecx
add    esp, 28h
retn
```

By C++ standard, destructor doesn’t return anything, but when Hex-Rays don’t know about it, and thinks that both destructor and this function returns *int*, we can see something like that in output:

```
... 
return CString::~CString(&Str);
```

### 1.15.2 What if we do not use the function result?

`printf()` returns the count of characters successfully output, but the result of this function is rarely used in practice.

It is also possible to call a function whose essence is in returning a value, and not use it:
int f()
{
    // skip first 3 random values:
    rand();
    rand();
    rand();
    // and use 4th:
    return rand();
};

The result of the rand() function is left in EAX, in all four cases.
But in the first 3 cases, the value in EAX is just not used.

1.15.3 Returning a structure

Let's go back to the fact that the return value is left in the EAX register.
That is why old C compilers cannot create functions capable of returning something that does not fit in one
register (usually int), but if one needs it, one have to return information via pointers passed as function's
arguments.
So, usually, if a function needs to return several values, it returns only one, and all the rest—via pointers.
Now it has become possible to return, let's say, an entire structure, but that is still not very popular. If
a function has to return a large structure, the caller must allocate it and pass a pointer to it via the first
argument, transparently for the programmer. That is almost the same as to pass a pointer in the first
argument manually, but the compiler hides it.
Small example:

struct s
{
    int a;
    int b;
    int c;
};

struct s get_some_values (int a)
{
    struct s rt;
    rt.a=a+1;
    rt.b=a+2;
    rt.c=a+3;
    return rt;
};

...what we got (MSVC 2010 /Ox):

$T3853 = 8 ; size = 4
_a$ = 12 ; size = 4

?get_some_values@@YA?AUs@H@Z PROC ; get_some_values
mov ecx, DWORD PTR _a$[esp-4]
mov eax, DWORD PTR $T3853[esp-4]
lea edx, DWORD PTR [ecx+1]
mov DWORD PTR [eax], edx
lea edx, DWORD PTR [ecx+2]
add ecx, 3
mov DWORD PTR [eax+4], edx
mov DWORD PTR [eax+8], ecx
ret 0
?get_some_values@@YA?AUs@H@Z ENDP ; get_some_values

The macro name for internal passing of pointer to a structure here is $T3853.
This example can be rewritten using the C99 language extensions:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
struct s {
    int a;
    int b;
    int c;
};

struct s get_some_values (int a) {
    return (struct s){.a=a+1, .b=a+2, .c=a+3};
};

Listing 1.101: GCC 4.8.1

_get_some_values proc near
ptr_to_struct = dword ptr 4
a = dword ptr 8
    mov    edx, [esp+a]
    mov    eax, [esp+ptr_to_struct]
    lea    ecx, [edx+1]
    mov    [eax], ecx
    lea    ecx, [edx+2]
    add    edx, 3
    mov    [eax+4], ecx
    mov    [eax+8], edx
retn
_get_some_values endp

As we see, the function is just filling the structure’s fields allocated by the caller function, as if a pointer to the structure has been passed. So there are no performance drawbacks.

1.16 Pointers

1.16.1 Returning values

Pointers are often used to return values from functions (recall scanf() case (1.12 on page 66)). For example, when a function needs to return two values.

Global variables example

#include <stdio.h>

void f1 (int x, int y, int *sum, int *product) {
    *sum=x+y;
    *product=x*y;
};

int sum, product;

void main() {
    f1(123, 456, &sum, &product);
    printf("sum=%d, product=%d\n", sum, product);
};

This compiles to:

Listing 1.102: Optimizing MSVC 2010 (/Ob0)

(COMM _product:DWORD)
; _sum:DWORD
$SG2803 DB 'sum=%d, product=%d', 0aH, 00H

_x$ = 8 ; size = 4
_y$ = 12 ; size = 4
_sum$ = 16 ; size = 4
_product$ = 20 ; size = 4

_f1 PROC
  mov ecx, DWORD PTR _y$[esp-4]
  mov eax, DWORD PTR _x$[esp-4]
  lea edx, DWORD PTR [eax+ecx]
  imul eax, ecx
  mov esi, DWORD PTR _product$[esp-4]
  push esi
  mov DWORD PTR [esi], edx
  mov DWORD PTR [ecx], eax
  pop esi
  ret 0

_f1 ENDP

_main PROC
  push OFFSET _product
  push OFFSET _sum
  push 456 ; 000001c8H
  push 123 ; 0000007bH
  call _f1
  mov eax, DWORD PTR _product
  mov ecx, DWORD PTR _sum
  push eax
  push ecx
  push OFFSET $SG2803
  call DWORD PTR __imp__printf
  add esp, 28
  xor eax, eax
  ret 0

_main ENDP

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s see this in OllyDbg:

First, global variables’ addresses are passed to f1(). We can click “Follow in dump” on the stack element, and we can see the place in the data segment allocated for the two variables.
These variables are zeroed, because non-initialized data (from BSS) is cleared before
the execution begins, [see ISO/IEC 9899:TC3 (C C99 standard), (2007) 6.7.8p10].

They reside in the data segment, we can verify this by pressing Alt-M and reviewing the memory map:

![Figure 1.26: OllyDbg: memory map](image)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's trace (F7) to the start of f1():

![Image of OllyDbg output]

**Figure 1.27: OllyDbg: f1() starts**

Two values are visible in the stack: 456 (0x1C8) and 123 (0x7B), and also the addresses of the two global variables.

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let’s trace until the end of \( f1() \). In the left bottom window we see how the results of the calculation appear in the global variables:

![CPU - main thread, module global](Image)

**Figure 1.28:** OllyDbg: \( f1() \) execution completed

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Now the global variables’ values are loaded into registers ready for passing to printf() (via the stack):

![CPU - main thread, module global](image)

**Figure 1.29: OllyDbg: global variables’ values are passed into printf()**

**Local variables example**

Let’s rework our example slightly:

```c
void main()
{
    int sum, product; // now variables are local in this function
    f1(123, 456, &sum, &product);
    printf("sum=\%d, product=\%d\n", sum, product);
}
```

f1() code will not change. Only the code of main() will do:

```c
Listing 1.104: Optimizing MSVC 2010 (/Ob0)

```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let's look again with OllyDbg. The addresses of the local variables in the stack are 0x2EF854 and 0x2EF858. We see how these are pushed into the stack:

![CPU - main thread, module local](image)

Figure 1.30: OllyDbg: local variables' addresses are pushed into the stack.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
f1() starts. So far there is only random garbage in the stack at 0x2EF854 and 0x2EF858:

Figure 1.31: OllyDbg: f1() starting
We now find 0xDB18 and 0x243 at addresses 0x2EF854 and 0x2EF858. These values are the f1() results.

Conclusion

f1() could return pointers to any place in memory, located anywhere.

This is in essence the usefulness of the pointers.

By the way, C++ references work exactly the same way. Read more about them: (3.19.3 on page 565).

1.16.2 Swap input values

This will do the job:

```c
#include <memory.h>
#include <stdio.h>

void swap_bytes (unsigned char* first, unsigned char* second) {
    unsigned char tmp1;
    unsigned char tmp2;
    
    tmp1=*first;
    tmp2=*second;
    
    *first=tmp2;
    *second=tmp1;
}

int main() {
    
    // copy string into heap, so we will be able to modify it
    char *s=strdup("string");
    
    // swap 2nd and 3rd characters
    swap_bytes (s+1, s+2);
    
    printf ("%s\n", s);
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As we can see, bytes are loaded into lower 8-bit parts of ECX and EBX using MOVZX (so higher parts of these registers will be cleared) and then bytes are written back swapped.

Listing 1.105: Optimizing GCC 5.4

```
swap_bytes:
    push ebx
    mov edx, DWORD PTR [esp+8]
    mov eax, DWORD PTR [esp+12]
    movzx ecx, BYTE PTR [edx]
    movzx ebx, BYTE PTR [eax]
    mov BYTE PTR [edx], bl
    mov BYTE PTR [eax], cl
    pop ebx
    ret
```

Addresses of both bytes are taken from arguments and through execution of the function are located in EDX and EAX.

So we use pointers: probably, there is no better way to solve this task without them.

### 1.17 GOTO operator

The GOTO operator is generally considered as anti-pattern, see [Edgar Dijkstra, Go To Statement Considered Harmful (1968)\(^89\)]. Nevertheless, it can be used reasonably, see [Donald E. Knuth, Structured Programming with go to Statements (1974)\(^90\)]\(^91\).

Here is a very simple example:

```
#include <stdio.h>

int main()
{
    printf("begin\n");
    goto exit;
    printf("skip me!\n");
    exit:
    printf("end\n");
}
```

Here is what we have got in MSVC 2012:

Listing 1.106: MSVC 2012

```
$SG2934 DB 'begin', 0aH, 00H
$SG2936 DB 'skip me!', 0aH, 00H
$SG2937 DB 'end', 0aH, 00H

_main PROC
    push ebp
    mov ebp, esp
    push OFFSET $SG2934 ; 'begin'
    call _printf
    add esp, 4
    jmp SHORT $exit$3
    push OFFSET $SG2936 ; 'skip me'
    call _printf
    add esp, 4
    $exit$3:
    push OFFSET $SG2937 ; 'end'
    call _printf
    add esp, 4
    xor eax, eax
```

\(^89\)[http://yurichev.com/mirrors/Dijkstra68.pdf]
\(^90\)[http://yurichev.com/mirrors/KnuthStructuredProgrammingGoTo.pdf]
\(^91\)[Dennis Yurichev, C/C++ programming language notes] also has some examples.
The `goto` statement has been simply replaced by a JMP instruction, which has the same effect: unconditional jump to another place. The second `printf()` could be executed only with human intervention, by using a debugger or by patching the code.
This could also be useful as a simple patching exercise. Let’s open the resulting executable in Hiew:

![Hiew: goto.exe](image)

### Figure 1.33: Hiew
Place the cursor to address JMP (0x410), press F3 (edit), press zero twice, so the opcode becomes EB 00:

The second byte of the JMP opcode denotes the relative offset for the jump, 0 means the point right after the current instruction.

So now JMP not skipping the second printf() call.

Press F9 (save) and exit. Now if we run the executable we will see this:

Listing 1.107: Patched executable output

C:...>goto.exe
begin
skip me!
end

The same result could be achieved by replacing the JMP instruction with 2 NOP instructions.

NOP has an opcode of 0x90 and length of 1 byte, so we need 2 instructions as JMP replacement (which is 2 bytes in size).

### 1.17.1 Dead code

The second printf() call is also called “dead code” in compiler terms.

This means that the code will never be executed. So when you compile this example with optimizations, the compiler removes “dead code”, leaving no trace of it:

Listing 1.108: Optimizing MSVC 2012

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
However, the compiler forgot to remove the “skip me!” string.

### 1.17.2 Exercise

Try to achieve the same result using your favorite compiler and debugger.

### 1.18 Conditional jumps

#### 1.18.1 Simple example

```c
#include <stdio.h>

void f_signed (int a, int b)
{
    if (a>b)
        printf("a>b\n");
    if (a==b)
        printf("a==b\n");
    if (a<b)
        printf("a<b\n");
};

void f_unsigned (unsigned int a, unsigned int b)
{
    if (a>b)
        printf("a>b\n");
    if (a==b)
        printf("a==b\n");
    if (a<b)
        printf("a<b\n");
};

int main()
{
    f_signed(1, 2);
    f_unsigned(1, 2);
    return 0;
};
```

### x86

### x86 + MSVC

Here is how the `f_signed()` function looks like:

```
Listing 1.109: Non-optimizing MSVC 2010
.a$ = 8  
.b$ = 12  
.f_signed   PROC
    push   ebp
    mov    ebp, esp
    mov    eax, DWORD PTR _a$[ebp]
    cmp    eax, DWORD PTR _b$[ebp]
    jle    SHORT $LN3@f_signed
    push   OFFSET $SG737 ; 'a>b'
    call   _printf
    add    esp, 4
    ret           

(fory statistics collecting purposes) if you've read this far, please click here. Thanks!
```
The first instruction, JLE, stands for Jump if Less or Equal. In other words, if the second operand is larger or equal to the first one, the control flow will be passed to the address or label specified in the instruction. If this condition does not trigger because the second operand is smaller than the first one, the control flow would not be altered and the first printf() would be executed. The second check is JNE: Jump if Not Equal. The control flow will not change if the operands are equal.

The third check is JGE: Jump if Greater or Equal—jump if the first operand is larger than the second or if they are equal. So, if all three conditional jumps are triggered, none of the printf() calls would be executed whatsoever. This is impossible without special intervention. Now let’s take a look at the f_unsigned() function. The f_unsigned() function is the same as f_signed(), with the exception that the JBE and JAE instructions are used instead of JLE and JGE, as follows:

Listing 1.110: GCC

As already mentioned, the branch instructions are different: JBE—Jump if Below or Equal and JAE—Jump if Above or Equal. These instructions (JA/JAE/JB/JBE) differ from JG/JGE/ JL/JLE in the fact that they work with unsigned numbers.

See also the section about signed number representations (2.2 on page 458). That is why if we see JG/JL in use instead of JA/JB or vice-versa, we can be almost sure that the variables are signed or unsigned, respectively. Here is also the main() function, where there is nothing much new to us:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.111: main()

```
_main PROC
  push  ebp
  mov   ebp, esp
  push  2
  push  1
  call _f_signed
  add   esp, 8
  push  2
  push  1
  call _f_unsigned
  add   esp, 8
  xor   eax, eax
  pop   ebp
  ret   0

main ENDP
```
We can see how flags are set by running this example in OllyDbg. Let's begin with `f_unsigned()`, which works with unsigned numbers.

`CMP` is executed thrice here, but for the same arguments, so the flags are the same each time. Result of the first comparison:

![CPU - main thread, module ex](image)

**Figure 1.35: OllyDbg: f_unsigned(): first conditional jump**

So, the flags are: C=1, P=1, A=1, Z=0, S=1, T=0, D=0, O=0.

They are named with one character for brevity in OllyDbg.

OllyDbg gives a hint that the (JBE) jump is to be triggered now. Indeed, if we take a look into Intel manuals (12.1.4 on page 986), we can read there that JBE is triggering if CF=1 or ZF=1. The condition is true here, so the jump is triggered.
The next conditional jump:

Figure 1.36: OllyDbg: \texttt{f_unsigned}(): second conditional jump

OllyDbg gives a hint that JNZ is to be triggered now. Indeed, JNZ triggering if ZF=0 (zero flag).
The third conditional jump, JNB:

![Figure 1.37: OllyDbg: f_unsigned(): third conditional jump](image)

In Intel manuals (12.1.4 on page 986) we can see that JNB triggers if CF=0 (carry flag). That is not true in our case, so the third printf() will execute.
Now let's review the `f_signed()` function, which works with signed values, in OllyDbg. Flags are set in the same way: C=1, P=1, A=1, Z=0, S=1, T=0, D=0, O=0. The first conditional jump JLE is to be triggered:

Figure 1.38: OllyDbg: `f_signed()`: first conditional jump

In Intel manuals (12.1.4 on page 986) we find that this instruction is triggered if ZF=1 or SF≠OF. SF≠OF in our case, so the jump triggers.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The second JNZ conditional jump triggering: if ZF=0 (zero flag):

Figure 1.39: OllyDbg: f_signed(): second conditional jump

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
The third conditional jump JGE will not trigger because it would only do so if SF=OF, and that is not true in our case:

Figure 1.40: OllyDbg: f_signed(): third conditional jump
We can try to patch the executable file in a way that the `f_unsigned()` function would always print “a==b”, no matter the input values. Here is how it looks in Hiew:

![Hiew: f_unsigned() function](image)

**Figure 1.41: Hiew: f_unsigned() function**

Essentially, we have to accomplish three tasks:

- force the first jump to always trigger;
- force the second jump to never trigger;
- force the third jump to always trigger.

Thus we can direct the code flow to always pass through the second `printf()`, and output “a==b”.

Three instructions (or bytes) has to be patched:

- The first jump becomes `JMP`, but the **jump offset** would remain the same.
- The second jump might be triggered sometimes, but in any case it will jump to the next instruction, because, we set the **jump offset** to 0.
  
  In these instructions the **jump offset** is added to the address for the next instruction. So if the offset is 0, the jump will transfer the control to the next instruction.
- The third jump we replace with `JMP` just as we do with the first one, so it will always trigger.

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Here is the modified code:

Figure 1.42: Hiew: let's modify the f_unsigned() function

If we miss to change any of these jumps, then several printf() calls may execute, while we want to execute only one.

Non-optimizing GCC

Non-optimizing GCC 4.4.1 produces almost the same code, but with puts() (1.5.3 on page 20) instead of printf().

Optimizing GCC

An observant reader may ask, why execute CMP several times, if the flags has the same values after each execution?

Perhaps optimizing MSVC cannot do this, but optimizing GCC 4.8.1 can go deeper:

Listing 1.112: GCC 4.8.1 f_signed()

```
f_signed:
    mov    eax, DWORD PTR [esp+8]
    cmp    DWORD PTR [esp+4], eax
    jg     .L6
    je     .L7
    jge    .L1
mov    DWORD PTR [esp+4], OFFSET FLAT:.LC2 ; "a<b"
jmp    puts
.L6:
mov    DWORD PTR [esp+4], OFFSET FLAT:.LC0 ; "a>b"
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
We also see JMP puts here instead of CALL puts / RETN.
This kind of trick will have explained later: 1.21.1 on page 156.
This type of x86 code is somewhat rare. MSVC 2012 as it seems, can't generate such code. On the other hand, assembly language programmers are fully aware of the fact that Jcc instructions can be stacked.
So if you see such stacking somewhere, it is highly probable that the code was hand-written.
The f_unsigned() function is not that æsthetically short:

```assembly
Listing 1.113: GCC 4.8.1 f_unsigned()

f_unsigned:
push esi
push ebx
sub esp, 20
mov esi, DWORD PTR [esp+32]
mov ebx, DWORD PTR [esp+36]
cmp esi, ebx
ja .L13
cmp esi, ebx ; this instruction could be removed
ej .L14
.L10:
jb .L15
add esp, 20
pop ebx
pop esi
ret
.L15:
mov DWORD PTR [esp+32], OFFSET FLAT:.LC2 ; "a<b"
add esp, 20
pop ebx
pop esi
jmp puts
.L13:
mov DWORD PTR [esp], OFFSET FLAT:.LC0 ; "a>b"
call puts
cmp esi, ebx
jne .L10
.L14:
mov DWORD PTR [esp+32], OFFSET FLAT:.LC1 ; "a==b"
add esp, 20
pop ebx
pop esi
jmp puts
```

Nevertheless, there are two CMP instructions instead of three.
So optimization algorithms of GCC 4.8.1 are probably not perfect yet.

**ARM**

**32-bit ARM**

**Optimizing Keil 6/2013 (ARM mode)**

```assembly
Listing 1.114: Optimizing Keil 6/2013 (ARM mode)

.text:00000008     EXPORT f_signed

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Many instructions in ARM mode could be executed only when specific flags are set. E.g. this is often used when comparing numbers.

For instance, the ADD instruction is in fact named ADDAL internally, where AL stands for Always, i.e., execute always. The predicates are encoded in 4 high bits of the 32-bit ARM instructions (condition field). The B instruction for unconditional jumping is in fact conditional and encoded just like any other conditional jump, but has AL in the condition field, and it implies execute Always, ignoring flags.

The ADRGT instruction works just like ADR but executes only in case the previous CMP instruction founds one of the numbers greater than the other, while comparing the two (Greater Than).

The next BLGT instruction behaves exactly as BL and is triggered only if the result of the comparison has been (Greater Than). ADRGT writes a pointer to the string \texttt{a=b\textbackslash n} into R0 and BLGT calls printf(). Therefore, instructions suffixed with \texttt{-GT} are to execute only in case the value in R0 (which is \texttt{a}) is bigger than the value in R4 (which is \texttt{b}).

Moving forward we see the ADREQ and BLEQ instructions. They behave just like ADR and BL, but are to be executed only if operands were equal to each other during the last comparison. Another CMP is located before them (because the printf() execution may have tampered the flags).

Then we see LDMGEFD, this instruction works just like LDMFD\textsuperscript{92}, but is triggered only when one of the values is greater or equal than the other (Greater or Equal). The LDMGEFD SP!, (R4-R6,PC) instruction acts like a function epilogue, but it will be triggered only if \texttt{a} \geq \texttt{b}, and only then the function execution will finish.

But if that condition is not satisfied, i.e., \texttt{a} \textless \texttt{b}, then the control flow will continue to the next “LDMFD SP!, (R4-R6,LR)” instruction, which is one more function epilogue. This instruction restores not only the R4-R6 registers state, but also LR instead of PC, thus, it does not return from the function. The last two instructions call printf() with the string \texttt{\textless b\textbackslash n} as a sole argument. We already examined an unconditional jump to the printf() function instead of function return in «printf() with several arguments» section (1.11.2 on page 54).

\texttt{f\_unsigned} is similar, only the ADRHI, BLHI, and LDMCSFD instructions are used there, these predicates (HI = UnSigned higher, CS = Carry Set (greater than or equal)) are analogous to those examined before, but for unsigned values.

There is not much new in the main() function for us:

\texttt{Listing 1.115: main()}

\begin{verbatim}
.f_text:000000B8 f_signed
  ; CODE XREF: main+C
.f_text:000000B8 70 40 2D E9 STMF D SP!, {R4-R6,LR}

.f_text:000000EC ; End of function f_signed

 etwa jedem der beiden Anlagen einen eigenen Raum zuorden, um ihn für das eigene Verwaltungszentrum zur Verfügung zu stellen. Dazu gehören die Bereiche der Arbeitsinhalte, die Ausstellungsflächen für die unterschiedlichen Abteilungen und die Verwaltungsbereiche, die für die Administration und Finanzen zuständig sind. Der Raum sollte dabei so gestaltet werden, dass er sowohl in der Arbeitswelt als auch in der häuslichen Umgebung für die Mitarbeiter einen angenehmen Arbeitsplatz bietet.

Für die Ausgestaltung der Räume sind spezialisierte Design-Büros und Architekturbüros tätig. Sie kümmern sich um den konzeptionellen und praktischen Aspekt, um sicherzustellen, dass die Räume funktionell und ästhetisch ansprechend gestaltet sind. Die Verwaltungszentrale sollte zum Beispiel transparent gemacht werden, um den Mitarbeiterinnen und Mitarbeitern eine bessere Sicht auf die Zusammenhänge und Prozesse in der Organisation zu ermöglichen. Der Raum sollte auch technische Anlagen wie Computersysteme, Telekommunikationsanlagen und Sicherheitssysteme integrieren, um die Effizienz und die Effektivität der Arbeit zu fördern.

Abschließend sei erwähnt, dass die Ausgestaltung der Räume nicht nur von der Architektur und dem Design, sondern auch von der physischen Gestaltung und der Organisation der Arbeitsabläufe abhängt. Die Verwaltungszentrale sollte so gestaltet werden, dass sie sowohl die praktischen Bedürfnisse der Mitarbeiter als auch die emotionalen Anforderungen des Unternehmens erfüllt. Die Mitarbeiterinnen und Mitarbeiter sollten in einem freundlichen und positiven Arbeitsumfeld arbeiten, das ihnen eine angenehme Arbeitswelt bietet und gleichzeitig die Effizienz und die produktive Arbeit fördert.
That is how you can get rid of conditional jumps in ARM mode.

Why is this so good? Read here: 2.10.1 on page 471.

There is no such feature in x86, except the CMOVcc instruction, it is the same as MOV, but triggered only when specific flags are set, usually set by CMP.

Optimizing Keil 6/2013 (Thumb mode)

Only B instructions in Thumb mode may be supplemented by condition codes, so the Thumb code looks more ordinary.

BLE is a normal conditional jump Less than or Equal, BNE—Not Equal, BGE—Greater than or Equal.

f_unsigned is similar, only other instructions are used while dealing with unsigned values: BLS (Unsigned lower or same) and BCS (Carry Set (Greater than or equal)).

ARM64: Optimizing GCC (Linaro) 4.9

```
Listing 1.117: f_signed()

```
f_signed:
; W0=a, W1=b
    cmp     w0, w1
    bgt     .L19 ; Branch if Greater Than (a>b)
    beq     .L20 ; Branch if Equal (a==b)
    bge     .L15 ; Branch if Greater than or Equal (a>=b) (impossible here)
    ; a<b
    adrp    x0, .LC11 ; "a<b"
    add     x0, x0, :lo12:.LC11
    b       puts
.L19:
    adrp    x0, .LC9 ; "a>b"
    add     x0, x0, :lo12:.LC9
    b       puts
.L15: ; impossible to get here
    ret
.L20:
    adrp    x0, .LC10 ; "a==b"
    add     x0, x0, :lo12:.LC10
    b       puts
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The comments were added by the author of this book. What is striking is that the compiler is not aware that some conditions are not possible at all, so there is dead code at some places, which can never be executed.

**Exercise**

Try to optimize these functions manually for size, removing redundant instructions, without adding new ones.

**MIPS**

One distinctive MIPS feature is the absence of flags. Apparently, it was done to simplify the analysis of data dependencies.

There are instructions similar to SETcc in x86: SLT ("Set on Less Than": signed version) and SLTU (unsigned version). These instructions sets destination register value to 1 if the condition is true or to 0 if otherwise. The destination register is then checked using BEQ ("Branch on Equal") or BNE ("Branch on Not Equal") and a jump may occur. So, this instruction pair has to be used in MIPS for comparison and branch. Let's first start with the signed version of our function:

**Listing 1.119: Non-optimizing GCC 4.4.5 (IDA)**

```
.text:00000000  f_signed:  # CODE XREF: main+18
    .text:00000000  var_10 = -0x10
    .text:00000000  var_8  = -8
    .text:00000000  var_4  = -4
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
print "a>b" and finish

$at, $zero ; NOP

; this is pseudo-instruction. in fact, "slt $v0,$v0,$v1" is there.
; so $v0 will be set to 1 if $v0<$v1 (b<a) or to 0 if otherwise:

slt $v0, $v1

; jump to loc_5C, if condition is not true.
; this is pseudo-instruction. in fact, "beq $v0,$zero,loc_5C" is there:

beqz $v0, loc_5C; print "a-b" and finish

or $at, $zero ; branch delay slot, NOP

lui $v0, (unk_230 >> 16) # "a>b"

addiu $a0, $v0, (unk_230 & 0xFFFF) # "a>b"

lw $v0, (puts & 0xFFFF)($gp)

or $at, $zero ; NOP

move $t9, $v0

jalr $t9

or $at, $zero ; branch delay slot, NOP

lw $sp, 0x20+arg_4($gp)

; check if a=b, jump to loc_90 if its not true:

bne $v1, $v0, loc_90

or $at, $zero ; branch delay slot, NOP

; condition is true, so print "a=b" and finish:

lui $v0, (aAB >> 16) # "a=b"

addiu $a0, $v0, (aAB & 0xFFFF) # "a=b"

lw $v0, (puts & 0xFFFF)($gp)

or $at, $zero ; NOP

move $t9, $v0

jalr $t9

or $at, $zero ; branch delay slot, NOP

lw $gp, 0x20+var_10($fp)

; check if $v1<$v0 (a<b), set $v0 to 1 if condition is true:

slt $v0, $v1, $v0

; if condition is not true (i.e., $v0==0), jump to loc_c8:

beqz $v0, loc_c8

or $at, $zero ; branch delay slot, NOP

; condition is true, print "a-b" and finish

lui $v0, (aAB_0 >> 16) # "a<b"

addiu $a0, $v0, (aAB_0 & 0xFFFF) # "a<b"

lw $v0, (puts & 0xFFFF)($gp)

or $at, $zero ; NOP

move $t9, $v0

jalr $t9

or $at, $zero ; branch delay slot, NOP

lw $gp, 0x20+var_10($fp)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We also see there BEQ pseudo instruction (“Branch if Equal to Zero”), which are in fact BEQ REG, $ZERO, LABEL.

The unsigned version is just the same, but SLTU (unsigned version, hence “U” in name) is used instead of SLT:

Listing 1.120: Non-optimizing GCC 4.4.5 (IDA)
1.18.2 Calculating absolute value

A simple function:

```c
int my_abs (int i)
{
    if (i<0)
        return -i;
    else
        return i;
}
```

Optimizing MSVC

This is how the code is usually generated:

```
Listing 1.121: Optimizing MSVC 2012 x64

i$ = 8
my_abs PROC
    ; ECX = input
    test ecx, ecx
    ; check for sign of input value
    ; skip NEG instruction if sign is positive
    jns SHORT $LN2@my_abs
    ; negate value
    neg ecx
$LN2@my_abs:
    ; prepare result in EAX:
    mov eax, ecx
    ret
my_abs ENDP
```

GCC 4.9 does mostly the same.

Optimizing Keil 6/2013: Thumb mode

```
Listing 1.122: Optimizing Keil 6/2013: Thumb mode

my_abs PROC
    CMP r0,#0
    ; is input value equal to zero or greater than zero?
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
ARM lacks a negate instruction, so the Keil compiler uses the “Reverse Subtract” instruction, which just subtracts with reversed operands.

**Optimizing Keil 6/2013: ARM mode**

It is possible to add condition codes to some instructions in ARM mode, so that is what the Keil compiler does:

```
my_abs PROC
    cmp r0,#0
    ; execute "Reverse Subtract" instruction only if input value is less than 0:
    rsblt r0,r0,#0
    bx lr
ENDP
```

Now there are no conditional jumps and this is good: 2.10.1 on page 471.

**Non-optimizing GCC 4.9 (ARM64)**

ARM64 has instruction NEG for negating:

```
my_abs:
    sub sp, sp, #16
    str w0, [sp,12]
    ldr w0, [sp,12]
    ; compare input value with contents of WZR register
    ; (which always holds zero)
    cmp w0, wzr
    bge .L2
    neg w0, w0
    b .L3
.L2:
    ldr w0, [sp,12]
.L3:
    add sp, sp, 16
    ret
```

**MIPS**

```
my_abs:
    ; jump if $a0<0:
    bltz $a0, locret_10
    ; just return input value ($a0) in $v0:
    move $v0, $a0
    jr $ra
    or $at, $zero ; branch delay slot, NOP
locret_10:
    ; negate input value and store it in $v0:
    jr $ra
    ; this is pseudoinstruction. in fact, this is "subu $v0,$zero,$a0" ($v0=0-$a0)
    negu $v0, $a0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here we see a new instruction: **BLTZ** ("Branch if Less Than Zero").

There is also the **NEGU** pseudo instruction, which just does subtraction from zero. The “U” suffix in both **SUBU** and **NEGU** implies that no exception to be raised in case of integer overflow.

**Branchless version?**

You could have also a branchless version of this code. This we will review later: **3.14 on page 525**.

**1.18.3 Ternary conditional operator**

The ternary conditional operator in C/C++ has the following syntax:

```
expression ? expression : expression
```

Here is an example:

```c
const char* f (int a)
{
    return a==10 ? "it is ten" : "it is not ten";
}
```

**x86**

Old and non-optimizing compilers generate assembly code just as if an if/else statement was used:

Listing 1.126: Non-optimizing MSVC 2008

```asm
SG792 DB 'it is ten', 00H
SG793 DB 'it is not ten', 00H

 tv65 = -4 ; this will be used as a temporary variable
 a$ = 8

 f PROC
 push ebp
 mov ebp, esp
 push ecx
 ; compare input value with 10
 cmp DWORD PTR _a$[ebp], 10
 ; jump to $LN3@f if not equal
 jne SHORT $LN3@f
 ; store pointer to the string into temporary variable:
 mov DWORD PTR tv65[ebp], OFFSET SG746 ; 'it is ten'
 ; jump to exit
 jmp SHORT $LN4@f

$LN3@f:
 ; store pointer to the string into temporary variable:
 mov DWORD PTR tv65[ebp], OFFSET SG747 ; 'it is not ten'

$LN4@f:
 ; this is exit. copy pointer to the string from temporary variable to EAX.
 mov eax, DWORD PTR tv65[ebp]
 mov esp, ebp
 pop ebp
 ret 0

 f ENDP
```

Listing 1.127: Optimizing MSVC 2008

```asm
SG792 DB 'it is ten', 00H
SG793 DB 'it is not ten', 00H

 a$ = 8 ; size = 4

 f PROC
 ; compare input value with 10
 cmp DWORD PTR _a$[esp-4], 10
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
mov  eax, OFFSET $SG792 ; 'it is ten'
;jump to $LN4@f if equal
je   SHORT $LN4@f
mov  eax, OFFSET $SG793 ; 'it is not ten'
$LN4@f:
    ret  0
_f  ENDP

Newer compilers are more concise:

Listing 1.128: Optimizing MSVC 2012 x64

$SG1355 DB  'it is ten', 00H
$SG1356 DB  'it is not ten', 00H

a$ = 8
f PROC
; load pointers to the both strings
  lea  rdx, OFFSET FLAT:$SG1355 ; 'it is ten'
  lea  rax, OFFSET FLAT:$SG1356 ; 'it is not ten'
; compare input value with 10
  cmp   ecx, 10
; if equal, copy value from RDX ("it is ten")
; if not, do nothing. pointer to the string "it is not ten" is still in RAX as for now.
  cmove rax, rdx
  ret  0
f  ENDP

Optimizing GCC 4.8 for x86 also uses the CMOVcc instruction, while the non-optimizing GCC 4.8 uses conditional jumps.

ARM

Optimizing Keil for ARM mode also uses the conditional instructions ADRcc:

Listing 1.129: Optimizing Keil 6/2013 (ARM mode)

f PROC
; compare input value with 10
  CMP  r0,#0xa
; if comparison result is EQual, copy pointer to the "it is ten" string into R0
  ADREQ r0,|L0.16| ; "it is ten"
; if comparison result is Not Equal, copy pointer to the "it is not ten" string into R0
  ADRNE r0,|L0.28| ; "it is not ten"
  BX   lr
ENDP
|L0.16|
DCB   "it is ten",0

|L0.28|
DCB   "it is not ten",0

Without manual intervention, the two instructions ADREQ and ADRNE cannot be executed in the same run.

Optimizing Keil for Thumb mode needs to use conditional jump instructions, since there are no load instructions that support conditional flags:

Listing 1.130: Optimizing Keil 6/2013 (Thumb mode)

f PROC
; compare input value with 10
  CMP  r0,#0xa
; jump to |L0.8| if EQual
  BEQ  |L0.8|
  ADR  r0,|L0.12| ; "it is not ten"
  BX   lr
  |L0.8|
  ADR  r0,|L0.28| ; "it is ten"
  BX   lr
ENDP

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
ARM64

Optimizing GCC (Linaro) 4.9 for ARM64 also uses conditional jumps:

Listing 1.131: Optimizing GCC (Linaro) 4.9

```assembly
f:
    cmp    x0, 10           ; branch if equal
    beq    .L3              ; "it is ten"
    adrp   x0, .LC1         ; "it is not ten"
    add    x0, x0, :lo12:.LC1
    ret
.L3:
    adrp   x0, .LC0         ; "it is not ten"
    add    x0, x0, :lo12:.LC0
    ret
.LC0:
    .string "it is ten"
.LC1:
    .string "it is not ten"
```

That is because ARM64 does not have a simple load instruction with conditional flags, like ADRcc in 32-bit ARM mode or CMOVcc in x86.

It has, however, “Conditional SE lect” instruction (CSEL)[ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile, (2013)p390, C5.5], but GCC 4.9 does not seem to be smart enough to use it in such piece of code.

MIPS

Unfortunately, GCC 4.4.5 for MIPS is not very smart, either:

Listing 1.132: Optimizing GCC 4.4.5 (assembly output)

```assembly
$LCO:  .ascii "it is not ten\000"
$LCL:  .ascii "it is ten\000"

f:
    li     $2,10             # 0xa
    ; compare $a0 and 10, jump if equal:
    beq    $4,$2,$L2
    nop    ; branch delay slot

    ; leave address of "it is not ten" string in $v0 and return:
    lui    $2,%hi($LCO)
    j      $31
    addiu  $2,$2,%lo($LCO)

$L2:
    ; leave address of "it is ten" string in $v0 and return:
    lui    $2,%hi($LCL)
    j      $31
    addiu  $2,$2,%lo($LCL)
```

Let's rewrite it in an if/else way

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
const char* f (int a)
{
    if (a==10)
        return "it is ten";
    else
        return "it is not ten";
};

Interestingly, optimizing GCC 4.8 for x86 was also able to use CMOVcc in this case:

Listing 1.133: Optimizing GCC 4.8

.LC0:
    .string "it is ten"
.LC1:
    .string "it is not ten"
f:
.LFB0:
    ; compare input value with 10
    cmp    DWORD PTR [esp+4], 10
    mov    edx, OFFSET FLAT:.LC1 ; "it is not ten"
    mov    eax, OFFSET FLAT:.LC0 ; "it is ten"
    ; if comparison result is Not Equal, copy EDX value to EAX
    ; if not, do nothing
    cmovne eax, edx
    ret

Optimizing Keil in ARM mode generates code identical to listing 1.129.
But the optimizing MSVC 2012 is not that good (yet).

Conclusion

Why optimizing compilers try to get rid of conditional jumps? Read here about it: 2.10.1 on page 471.

1.18.4 Getting minimal and maximal values

32-bit

int my_max(int a, int b)
{
    if (a>b)
        return a;
    else
        return b;
};

int my_min(int a, int b)
{
    if (a<b)
        return a;
    else
        return b;
};

Listing 1.134: Non-optimizing MSVC 2013

_a$ = 8
_b$ = 12
_my_min PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    ; compare A and B:
    cmp     eax, DWORD PTR _b$[ebp]
    ; jump, if A is greater or equal to B:
    (For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
jge SHORT $LN2@my_min
    ; reload A to EAX if otherwise and jump to exit
    mov eax, DWORD PTR _a$[ebp]
    jmp SHORT $LN3@my_min
    jmp SHORT $LN3@my_min ; this is redundant JMP
$LN2@my_min:
    ; return B
    mov eax, DWORD PTR _b$[ebp]
$LN3@my_min:
    pop ebp
    ret 0
_my_min ENDP

_a$ = 8
_b$ = 12
_my_max PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _a$[ebp]
    ; compare A and B:
    cmp eax, DWORD PTR _b$[ebp]
    ; jump if A is less or equal to B:
    jle SHORT $LN2@my_max
    ; reload A to EAX if otherwise and jump to exit
    mov eax, DWORD PTR _a$[ebp]
    jmp SHORT $LN3@my_max
    jmp SHORT $LN3@my_max ; this is redundant JMP
$LN2@my_max:
    ; return B
    mov eax, DWORD PTR _b$[ebp]
$LN3@my_max:
    pop ebp
    ret 0
_my_max ENDP

These two functions differ only in the conditional jump instruction: JGE (“Jump if Greater or Equal”) is used in the first one and JLE (“Jump if Less or Equal”) in the second.

There is one unneeded JMP instruction in each function, which MSVC presumably left by mistake.

Branchless

ARM for Thumb mode reminds us of x86 code:

my_max PROC
    ; R0=A
    ; R1=B
    ; compare A and B:
    CMP r0, r1
    ; branch if A is greater than B:
    BGT |L0.6|
    ; otherwise (A<=B) return R1 (B):
    MOVVS r0, r1
    |L0.6|
    ; return
    BX lr
ENDP

my_min PROC
    ; R0=A
    ; R1=B
    ; compare A and B:
    CMP r0, r1
    ; branch if A is less than B:
    BLT |L0.14|
    ; otherwise (A>=B) return R1 (B):
    MOVVS r0, r1
    |L0.14|

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The functions differ in the branching instruction: BGT and BLT. It’s possible to use conditional suffixes in ARM mode, so the code is shorter.

MOVcc is to be executed only if the condition is met:

Listing 1.136: Optimizing Keil 6/2013 (ARM mode)

```assembly
my_max PROC
    ; R0=A
    ; R1=B
    ; compare A and B:
    CMP r0,r1
    ; return B instead of A by placing B in R0
    ; this instruction will trigger only if A<=B (hence, LE - Less or Equal)
    ; if instruction is not triggered (in case of A>B), A is still in R0 register
    MOVLE r0,r1
    BX lr
ENDP

my_min PROC
    ; R0=A
    ; R1=B
    ; compare A and B:
    CMP r0,r1
    ; return B instead of A by placing B in R0
    ; this instruction will trigger only if A>=B (hence, GE - Greater or Equal)
    ; if instruction is not triggered (in case of A<B), A value is still in R0 register
    MOVGE r0,r1
    BX lr
ENDP
```

Optimizing GCC 4.8.1 and optimizing MSVC 2013 can use CMOVcc instruction, which is analogous to MOVcc in ARM:

Listing 1.137: Optimizing MSVC 2013

```assembly
my_max:
    mov edx, DWORD PTR [esp+4]
    mov eax, DWORD PTR [esp+8]
    ; EDX=A
    ; EAX=B
    ; compare A and B:
    cmp edx, eax
    ; if A>=B, load A value into EAX
    ; the instruction idle if otherwise (if A<B)
    cmovge eax, edx
    ret

my_min:
    mov edx, DWORD PTR [esp+4]
    mov eax, DWORD PTR [esp+8]
    ; EDX=A
    ; EAX=B
    ; compare A and B:
    cmp edx, eax
    ; if A<=B, load A value into EAX
    ; the instruction idle if otherwise (if A>B)
    cmovle eax, edx
    ret
```

64-bit

```c
#include <stdint.h>
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
int64_t my_max(int64_t a, int64_t b)
{
    if (a>b)
        return a;
    else
        return b;
};

int64_t my_min(int64_t a, int64_t b)
{
    if (a<b)
        return a;
    else
        return b;
};

There is some unneeded value shuffling, but the code is comprehensible:

Listing 1.138: Non-optimizing GCC 4.9.1 ARM64

my_max:
    sub    sp, sp, #16
    str    x0, [sp,8]
    str    x1, [sp]
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    cmp    x1, x0
    ble    .L2
    ldr    x0, [sp,8]
    b      .L3
.L2:
    ldr    x0, [sp]
.L3:
    add    sp, sp, 16
    ret

my_min:
    sub    sp, sp, #16
    str    x0, [sp,8]
    str    x1, [sp]
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    cmp    x1, x0
    bge    .L5
    ldr    x0, [sp,8]
    b      .L6
.L5:
    ldr    x0, [sp]
.L6:
    add    sp, sp, 16
    ret

Branchless

No need to load function arguments from the stack, as they are already in the registers:

Listing 1.139: Optimizing GCC 4.9.1 x64

my_max:
    ; RDI=A
    ; RSI=B
    ; compare A and B:
    cmp    rdi, rsi
    ; prepare B in RAX for return:
    mov    rax, rsi
    ; if A>B, put A (RDI) in RAX for return.
    ; this instruction is idle if otherwise (if A<B)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
   cmovge rax, rdi
   ret

my_min:
; RDI=A
; RSI=B
; compare A and B:
   cmp rdi, rsi
; prepare B in RAX for return:
   mov rax, rsi
; if A<=B, put A (RDI) in RAX for return.
; this instruction is idle if otherwise (if A>B)
   cmovle rax, rdi
   ret

MSVC 2013 does almost the same.

ARM64 has the CSEL instruction, which works just as MOVcc in ARM or CMOVcc in x86, just the name is different: “Conditional SELECT”.

Listing 1.140: Optimizing GCC 4.9.1 ARM64

my_max:
; X0=A
; X1=B
; compare A and B:
   cmp x0, x1
; select X0 (A) to X0 if X0>=X1 or A>=B (Greater or Equal)
; select X1 (B) to X0 if A<B
   csel x0, x0, x1, ge
   ret

my_min:
; X0=A
; X1=B
; compare A and B:
   cmp x0, x1
; select X0 (A) to X0 if X0<=X1 or A<=B (Less or Equal)
; select X1 (B) to X0 if A>B
   csel x0, x0, x1, le
   ret

MIPS

Unfortunately, GCC 4.4.5 for MIPS is not that good:

Listing 1.141: Optimizing GCC 4.4.5 (IDA)

my_max:
; set $v1 to 1 if $a1<$a0, or clear otherwise (if $a1>$a0):
   slt $v1, $a1, $a0
; jump, if $v1 is 0 (or $a1>$a0):
   beqz $v1, locret_10
; this is branch delay slot
; prepare $a1 in $v0 in case of branch triggered:
   move $v0, $a1
; no branch triggered, prepare $a0 in $v0:
   move $v0, $a0

locret_10:
   jr $ra
or $at, $zero ; branch delay slot, NOP

; the min() function is same, but input operands in SLT instruction are swapped:
my_min:
   slt $v1, $a0, $a1
   beqz $v1, locret_28
   move $v0, $a1
   move $v0, $a0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
1.18.5 Conclusion

x86

Here’s the rough skeleton of a conditional jump:

```
Listing 1.142: x86

CMP register, register/value
Jcc true ; cc=condition code
false:
... some code to be executed if comparison result is false ...
JMP exit
true:
... some code to be executed if comparison result is true ...
exit:
```

ARM

```
Listing 1.143: ARM

CMP register, register/value
Bcc true ; cc=condition code
false:
... some code to be executed if comparison result is false ...
JMP exit
true:
... some code to be executed if comparison result is true ...
exit:
```

MIPS

```
Listing 1.144: Check for zero

BEQZ REG, label
...
```

```
Listing 1.145: Check for less than zero using pseudoinstruction

BLTZ REG, label
...
```

```
Listing 1.146: Check for equal values

BEQ REG1, REG2, label
...
```

```
Listing 1.147: Check for non-equal values

BNE REG1, REG2, label
...
```

```
Listing 1.148: Check for less than (signed)

SLT REG1, REG2, REG3
BEQ REG1, label
...
```

Do not forget about the branch delay slots: the first MOVE is executed before BEQZ, the second MOVE is executed only if the branch hasn’t been taken.
Branchless

If the body of a condition statement is very short, the conditional move instruction can be used: MOVcc in ARM (in ARM mode), CSEL in ARM64, CMOVcc in x86.

ARM

It’s possible to use conditional suffixes in ARM mode for some instructions:

<table>
<thead>
<tr>
<th>Listing 1.150: ARM (ARM mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP register, register/value</td>
</tr>
<tr>
<td>instr1_cc ; some instruction will be executed if condition code is true</td>
</tr>
<tr>
<td>instr2_cc ; some other instruction will be executed if other condition code is true</td>
</tr>
<tr>
<td>... etc...</td>
</tr>
</tbody>
</table>

Of course, there is no limit for the number of instructions with conditional code suffixes, as long as the CPU flags are not modified by any of them.

Thumb mode has the IT instruction, allowing to add conditional suffixes to the next four instructions. Read more about it: 1.25.7 on page 263.

<table>
<thead>
<tr>
<th>Listing 1.151: ARM (Thumb mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP register, register/value</td>
</tr>
<tr>
<td>ITEEE EQ ; set these suffixes: if-then-else-else-else</td>
</tr>
<tr>
<td>instr1 ; instruction will be executed if condition is true</td>
</tr>
<tr>
<td>instr2 ; instruction will be executed if condition is false</td>
</tr>
<tr>
<td>instr3 ; instruction will be executed if condition is false</td>
</tr>
<tr>
<td>instr4 ; instruction will be executed if condition is false</td>
</tr>
</tbody>
</table>

1.18.6 Exercise

(ARM64) Try rewriting the code in listing 1.131 by removing all conditional jump instructions and using the CSEL instruction.

1.19 Software cracking

The vast majority of software can be cracked like that — by searching the very place where protection is checked, a dongle (8.5 on page 815), license key, serial number, etc.

Often, it looks like:

```plaintext
... call check_protection jz all_OK call message_box_protection_missing call exit all_OK: ; proceed ...
```

So if you see a patch (or “crack”), that cracks a software, and that patch replaces 0x74/0x75 (JZ/JNZ) byte(s) by 0xEB (JMP), this is it.

The process of software cracking comes down to a search of that JMP.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There are also a cases, when a software checks protection from time to time, this can be a dongle, or a license server can be queried through the Internet. Then you have to look for a function that checks protection. Then to patch it, to put there xor eax, eax / retn, or mov eax, 1 / retn.

It’s important to understand that after patching of function beginning, usually, a garbage follows these two instructions. The garbage consists of part of one instruction and the several next instructions. This is a real case. The beginning of a function which we want to replace by return 1;

```
Listing 1.152: Before

8BFF       mov       edi,edi
55         push      ebp
8BEC       mov       ebp,esp
81EC8800000  sub       esp,000000068
A110C00001  mov       eax,[00100C010]
33C5       xor       eax,ebp
8945FC     mov       [ebp][-4],eax
53         push      ebx
8B5D08     mov       ebx,[ebp][8]
...
```

```
Listing 1.153: After

8B01000000  mov       eax,1
C3         retn
EC         in        al,dx
68000000A1  push      0A100008
10C0       adc       al,al
0001       add       [ecx],al
33C5       xor       eax,ebp
8945FC     mov       [ebp][-4],eax
53         push      ebx
8B5D08     mov       ebx,[ebp][8]
...
```

Several incorrect instructions appears — IN, PUSH, ADC, ADD, after which, Hiew disassembler (which I just used) synchronized and continued to disassemble all the rest.

This is not important — all these instructions followed RETN will never be executed, unless a direct jump would occur from some place, and that wouldn’t be possible in general case.

Also, a global boolean variable can be present, having a flag, was the software registered or not.

```
init_etc proc
...
call check_protection_or_license_file
mov      is_demo, eax
...
retn
init_etc endp
...

save_file proc
...
mov      eax, is_demo
cmp      eax, 1
jz      all_OK1

call message_box_it_is_a_demo_no_saving_allowed
retn

:all_OK1
; continue saving file
...
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
save_proc endp

somewhere_else proc

mov eax, is_demo
cmp eax, 1
jz all_OK

; check if we run for 15 minutes
; exit if it is so
; or show nagging screen
:all_OK2
; continue

somewhere_else endp

A beginning of the check_protection_or_license_file() function could be patched, so that it will always return 1, or, if this is better by some reason, all JZ/JNZ instructions can be patched as well.

1.20 Impossible shutdown practical joke (Windows 7)

I don’t quite remember how I found the ExitWindowsEx() function in Windows 98’s (it was late 1990s) user32.dll file. Probably, I just spotted its self-describing name. And then I tried to block it by patching its beginning by 0xC3 byte (RETN).

The result was funny: Windows 98 cannot be shutted down anymore. Had to press reset button.

These days I tried to do the same in Windows 7, that was created almost 10 years later and based on completely different Windows NT base. Still, ExitWindowsEx() function present in user32.dll file and serves the same purpose.

First, I turned off Windows File Protection by adding this to registry (Windows would silently restore modified system files otherwise):

Windows Registry Editor Version 5.00

[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon]
"SFCDisable"=dword:ffffff9d

Then I renamed c:\windows\system32\user32.dll to user32.dll.bak. I found ExitWindowsEx() export entry using Hiew (IDA can help as well) and put 0xC3 byte here. I restarted by Windows 7 and now it can’t be shutted down. “Restart” and “Logoff” buttons don’t work anymore.

I don’t know if it’s funny today or not, but back then, in late 1990s, my friend took patched user32.dll file on a floppy diskette and copied it to all the computers (within his reach, that worked under Windows 98 (almost all)) at his university. No Windows can be shutted down after and his computer science teacher was extremely lurid. (Hopefully he can forgive us if he is reading this right now.)

If you do this, backup everything. The best idea is to run Windows under a virtual machine.

1.21 switch()/case/default

1.21.1 Small number of cases

#include <stdio.h>

void f (int a)
{
    switch (a)
    {
    case 0: printf ("zero\n"); break;
    case 1: printf ("one\n"); break;
    case 2: printf ("two\n"); break;

}
default: printf ("something unknown\n"); break;
}

int main()
{
    f (2); // test
}

**x86**

**Non-optimizing MSVC**

Result (MSVC 2010):

```
Listing 1.154: MSVC 2010

tv64 = -4 ; size = 4
_a$ = 8 ; size = 4
_f PROC
    push ebp
    mov ebp, esp
    push ecx
    mov eax, DWORD PTR _a$[ebp]
    mov DWORD PTR tv64[ebp], eax
    cmp DWORD PTR tv64[ebp], 0
    je SHORT $LN4@f
    cmp DWORD PTR tv64[ebp], 1
    je SHORT $LN3@f
    cmp DWORD PTR tv64[ebp], 2
    je SHORT $LN2@f
    jmp SHORT $LN1@f
$LN4@f:
    push OFFSET $SG739 ; 'zero', 0AH, 00H
    call _printf
    add esp, 4
    jmp SHORT $LN7@f
$LN3@f:
    push OFFSET $SG741 ; 'one', 0AH, 00H
    call _printf
    add esp, 4
    jmp SHORT $LN7@f
$LN2@f:
    push OFFSET $SG743 ; 'two', 0AH, 00H
    call _printf
    add esp, 4
    jmp SHORT $LN7@f
$LN1@f:
    push OFFSET $SG745 ; 'something unknown', 0AH, 00H
    call _printf
    add esp, 4
$LN7@f:
    mov esp, ebp
    pop ebp
    ret 0
_f ENDP
```

Our function with a few cases in switch() is in fact analogous to this construction:

```c
void f (int a)
{
    if (a==0)
        printf ("zero\n");
    else if (a==1)
        printf ("one\n");
    else if (a==2)
        printf ("two\n");
    else
```
printf ("something unknown\n");
};

If we work with switch() with a few cases it is impossible to be sure if it was a real switch() in the source code, or just a pack of if() statements.

This implies that switch() is like syntactic sugar for a large number of nested if()s.

There is nothing especially new to us in the generated code, with the exception of the compiler moving input variable \textit{a} to a temporary local variable \textit{tv64}.^93

If we compile this in GCC 4.4.1, we'll get almost the same result, even with maximal optimization turned on (-O3 option).

\section*{Optimizing MSVC}

Now let's turn on optimization in MSVC (/Ox):

```
cl 1.c /Fa1.asm /Ox
```

\begin{verbatim}
a$ = 8 ; size = 4
_f PROC
    mov    eax, DWORD PTR _a$[esp-4]
    sub    eax, 0
    je SHORT $LN4@f
    sub    eax, 1
    je SHORT $LN3@f
    sub    eax, 1
    je SHORT $LN2@f
    mov    DWORD PTR _a$[esp-4], OFFSET $SG791 ; 'something unknown', 0aH, 00H
    jmp    _printf
$LN2@f:
    mov    DWORD PTR _a$[esp-4], OFFSET $SG789 ; 'two', 0aH, 00H
    jmp    _printf
$LN3@f:
    mov    DWORD PTR _a$[esp-4], OFFSET $SG787 ; 'one', 0aH, 00H
    jmp    _printf
$LN4@f:
    mov    DWORD PTR _a$[esp-4], OFFSET $SG785 ; 'zero', 0aH, 00H
    jmp    _printf
_f ENDP
```

Here we can see some dirty hacks.

First: the value of \textit{a} is placed in EAX and 0 is subtracted from it. Sounds absurd, but it is done to check if the value in EAX is 0. If yes, the ZF flag is to be set (e.g. subtracting from 0 is 0) and the first conditional jump JE (\textit{Jump if Equal} or synonym JZ —\textit{Jump if Zero}) is to be triggered and control flow is to be passed to the $LN4@f$ label, where the 'zero' message is being printed. If the first jump doesn't get triggered, 1 is subtracted from the input value and if at some stage the result is 0, the corresponding jump is to be triggered.

And if no jump gets triggered at all, the control flow passes to \texttt{printf()} with string argument 'something unknown'.

Second: we see something unusual for us: a string pointer is placed into the \textit{a} variable, and then \texttt{printf()} is called not via CALL, but via JMP. There is a simple explanation for that: the \texttt{caller} pushes a value to the stack and calls our function via CALL. CALL itself pushes the return address (RA) to the stack and does an unconditional jump to our function address. Our function at any point of execution (since it do not contain any instruction that moves the stack pointer) has the following stack layout:

\begin{itemize}
  \item ESP—points to RA
  \item ESP+4—points to the \textit{a} variable
\end{itemize}

On the other side, when we have to call \texttt{printf()} here we need exactly the same stack layout, except for the first \texttt{printf()} argument, which needs to point to the string. And that is what our code does.

It replaces the function's first argument with the address of the string and jumps to \texttt{printf()}, as if we didn't call our function \texttt{f()}, but directly \texttt{printf()}. \texttt{printf()} prints a string to \texttt{stdout} and then executes

\footnotesize
\textsuperscript{93}Local variables in stack are prefixed with tv—that's how MSVC names internal variables for its needs

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
the RET instruction, which POPs RA from the stack and control flow is returned not to f() but rather to f()'s caller, bypassing the end of the f() function.

All this is possible because printf() is called right at the end of the f() function in all cases. In some way, it is similar to the longjmp() function. And of course, it is all done for the sake of speed.

A similar case with the ARM compiler is described in “printf() with several arguments” section, here (1.11.2 on page 54).

94wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
OllyDbg

Since this example is tricky, let's trace it in OllyDbg.

OllyDbg can detect such switch() constructs, and it can add some useful comments. EAX is 2 at the beginning, that's the function's input value:

![CPU - main thread, module few](image)

<table>
<thead>
<tr>
<th>Address</th>
<th>Hex dump</th>
<th>ASCII</th>
<th>ASCII len</th>
</tr>
</thead>
<tbody>
<tr>
<td>PPFF3000</td>
<td>74 77 6F 66</td>
<td>switch loses 0...5</td>
<td>switch loses 0...5</td>
</tr>
<tr>
<td>PPFF3000</td>
<td>67 6F 72 6C 64 65 67</td>
<td>&quot;something unknown&quot;</td>
<td>&quot;something unknown&quot;</td>
</tr>
<tr>
<td>PPFF3000</td>
<td>72 0</td>

</tr>
<tr>
<td>PPFF3000</td>
<td>72 0</td>
<td>EAX now contain the first (and only) function argument</td>
<td>EAX now contain the first (and only) function argument</td>
</tr>
</tbody>
</table>

Figure 1.43: OllyDbg: EAX now contain the first (and only) function argument

(For statistics collecting purposes) if you’ve read this far, please click [here](link). Thanks!
0 is subtracted from 2 in EAX. Of course, EAX still contains 2. But the ZF flag is now 0, indicating that the resulting value is non-zero:

Figure 1.44: OllyDbg: SUB executed

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
DEC is executed and EAX now contains 1. But 1 is non-zero, so the ZF flag is still 0:

Figure 1.45: OllyDbg: first DEC executed

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Next DEC is executed. EAX is finally 0 and the ZF flag gets set, because the result is zero:

OllyDbg shows that this jump is to be taken now.

Figure 1.46: OllyDbg: second DEC executed

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
A pointer to the string “two” is to be written into the stack now:

Please note: the current argument of the function is 2 and 2 is now in the stack at the address 0x001EF850.

Figure 1.47: OllyDbg: pointer to the string is to be written at the place of the first argument

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
MOV writes the pointer to the string at address 0x001EF850 (see the stack window). Then, jump happens. This is the first instruction of the printf() function in MSVCR100.DLL (This example was compiled with /MD switch):

![CPU - main thread, module MSVCR100](image)

Table 2.48: OllyDbg: first instruction of printf() in MSVCR100.DLL

Now printf() treats the string at 0x00FF3010 as its only argument and prints the string.
This is the last instruction of `printf()`:

The string “two” has just been printed to the console window.

---

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
Now let's press F7 or F8 (step over) and return...not to f(), but rather to main():

Yes, the jump has been direct, from the guts of printf() to main(). Because RA in the stack points not to some place in f(), but rather to main(). And CALL 0x00FF1000 has been the actual instruction which called f().

ARM: Optimizing Keil 6/2013 (ARM mode)

Again, by investigating this code we cannot say if it was a switch() in the original source code, or just a pack of if() statements.

Anyway, we see here predicated instructions again (like ADREQ (Equal)) which is triggered only in case R0 = 0, and then loads the address of the string «zero\n» into R0. The next instruction BEQ redirects control flow to loc_170, if R0 = 0.

An astute reader may ask, will BEQ trigger correctly since ADREQ it has already filled the R0 register before with another value?

Yes, it will since BEQ checks the flags set by the CMP instruction, and ADREQ does not modify any flags at all.

The rest of the instructions are already familiar to us. There is only one call to printf(), at the end, and we have already examined this trick here (1.11.2 on page 54). At the end, there are three paths to printf().

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The last instruction, `CMP R0, #2`, is needed to check if \( a = 2 \).

If it is not true, then `ADRNE` loads a pointer to the string `«something unknown \n»` into R0, since \( a \) has already been checked to be equal to 0 or 1, and we can sure that the \( a \) variable is not equal to these numbers at this point. And if \( R0 = 2 \), a pointer to the string `«two\n»` will be loaded by `ADREQ` into R0.

**ARM: Optimizing Keil 6/2013 (Thumb mode)**

```
.text:000000D4  f1:
.text:000000D4 10 B5  PUSH {R4,LR}
.text:000000D6 00 28  CMP R0, #0
.text:000000D8 05 D0  BEQ zero_case
.text:000000DA 01 28  CMP R0, #1
.text:000000DC 05 D0  BEQ one_case
.text:000000DE 02 28  CMP R0, #2
.text:000000E0 05 D0  BEQ two_case
.text:000000E2 91 A0  ADR R0, aSomethingUnkno ; "something unknown
"
.text:000000E4 04 E0  B default_case

.text:000000E6  zero_case: ; CODE XREF: f1+4
.text:000000E6 95 A0  ADR R0, aZero ; "zero"
.text:000000E8 02 E0  B default_case

.text:000000EA  one_case: ; CODE XREF: f1+8
.text:000000EA 96 A0  ADR R0, aOne ; "one"
.text:000000EC 00 E0  B default_case

.text:000000EE  two_case: ; CODE XREF: f1+C
.text:000000EE 97 A0  ADR R0, aTwo ; "two"
.text:000000EF 00 E0  B default_case ; CODE XREF: f1+10
.text:000000EF 06 F0 7E F8   BL __2printf
.text:000000F0 10 BD   POP {R4,PC}
```

As was already mentioned, it is not possible to add conditional predicates to most instructions in Thumb mode, so the Thumb-code here is somewhat similar to the easily understandable x86 CISC-style code.

**ARM64: Non-optimizing GCC (Linaro) 4.9**

```
.LC12:
    .string "zero"
.LC13:
    .string "one"
.LC14:
    .string "two"
.LC15:
    .string "something unknown"
.f12:
    stp x29, x30, [sp, -32]!
    add x29, sp, 0
    str w0, [x29,28]
    ldr w0, [x29,28]
    cmp w0, 1
    beq .L34
    cmp w0, 2
    beq .L35
    cmp w0, wzr
    bne .L38 ; jump to default label
    adrp x0, .LC12 ; "zero"
    add x0, x0, :lo12:.LC12
    bl puts
    b .L32

.L34:
    adrp x0, .LC13 ; "one"
    add x0, x0, :lo12:.LC13
    bl puts
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The type of the input value is int, hence register W0 is used to hold it instead of the whole X0 register.

The string pointers are passed to puts() using an ADRP/ADD instructions pair just like it was demonstrated in the “Hello, world!” example: 1.5.3 on page 23.

**ARM64: Optimizing GCC (Linaro) 4.9**

```
L35:
    adrp x0, .LC14 ; "two"
    add x0, x0, :lo12:.LC14
    bl puts
    b .L32

L38:
    adrp x0, .LC15 ; "something unknown"
    add x0, x0, :lo12:.LC15
    bl puts
    nop

L32:
    ldp x29, x30, [sp], 32
    ret
```

Better optimized piece of code. CBZ (Compare and Branch on Zero) instruction does jump if W0 is zero. There is also a direct jump to puts() instead of calling it, like it was explained before: 1.21.1 on page 156.

**MIPS**

```
Listing 1.156: Optimizing GCC 4.4.5 (IDA)

f:             lui $gp, (__gnu_local_gp >> 16)
; is it 1?
    li $v0, 1
    beq $a0, $v0, loc_60
    la $gp, (__gnu_local_gp & 0xFFFF) ; branch delay slot
; is it 2?
    li $v0, 2
    beq $a0, $v0, loc_4C
    or $at, $zero ; branch delay slot, NOP
; jump, if not equal to 0:
    bnez $a0, loc_38
    or $at, $zero ; branch delay slot, NOP
; zero case:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The function always ends with calling puts(), so here we see a jump to puts() (JR: “Jump Register”) instead of “jump and link”. We talked about this earlier: 1.21.1 on page 156.

We also often see NOP instructions after LW ones. This is “load delay slot”: another delayslot in MIPS.

An instruction next to LW may execute at the moment while LW loads value from memory.

However, the next instruction must not use the result of LW.

Modern MIPS CPUs have a feature to wait if the next instruction uses result of LW, so this is somewhat outdated, but GCC still adds NOPs for older MIPS CPUs. In general, it can be ignored.

Conclusion

A switch() with few cases is indistinguishable from an if/else construction, for example: listing.1.21.1.

1.21.2 A lot of cases

If a switch() statement contains a lot of cases, it is not very convenient for the compiler to emit too large code with a lot JE/JNE instructions.

#include <stdio.h>

void f (int a)
{
    switch (a)
    {
    case 0: printf ("zero\n"); break;
    case 1: printf ("one\n"); break;
    case 2: printf ("two\n"); break;
    case 3: printf ("three\n"); break;
    case 4: printf ("four\n"); break;
    default: printf ("something unknown\n"); break;
    }
};

int main()
{
    f (2); // test
}
Non-optimizing MSVC

We get (MSVC 2010):

Listing 1.157: MSVC 2010

tv64 = -4 ; size = 4
_a$ = 8 ; size = 4
_f PROC
  push ebp
  mov ebp, esp
  push ecx
  mov eax, DWORD PTR _a$[ebp]
  mov DWORD PTR tv64[ebp], eax
  cmp DWORD PTR tv64[ebp], 4
  ja SHORT $LN1@f
  mov ecx, DWORD PTR tv64[ebp]
  jmp DWORD PTR $LN11@f[ecx*4]
$LN6@f:
  push OFFSET $SG739 ; 'zero', 0AH, 00H
  call _printf
  add esp, 4
  jmp SHORT $LN9@f
$LN5@f:
  push OFFSET $SG741 ; 'one', 0AH, 00H
  call _printf
  add esp, 4
  jmp SHORT $LN9@f
$LN4@f:
  push OFFSET $SG743 ; 'two', 0AH, 00H
  call _printf
  add esp, 4
  jmp SHORT $LN9@f
$LN3@f:
  push OFFSET $SG745 ; 'three', 0AH, 00H
  call _printf
  add esp, 4
  jmp SHORT $LN9@f
$LN2@f:
  push OFFSET $SG747 ; 'four', 0AH, 00H
  call _printf
  add esp, 4
  jmp SHORT $LN9@f
$LN1@f:
  push OFFSET $SG749 ; 'something unknown', 0AH, 00H
  call _printf
  add esp, 4
$LN9@f:
  mov esp, ebp
  pop ebp
  ret 0
  npad 2 ; align next label
$LN11@f:
  DD $LN6@f ; 0
  DD $LN5@f ; 1
  DD $LN4@f ; 2
  DD $LN3@f ; 3
  DD $LN2@f ; 4
_f ENDP

What we see here is a set of printf() calls with various arguments. All they have not only addresses in the memory of the process, but also internal symbolic labels assigned by the compiler. All these labels are also mentioned in the $LN11@f internal table.

At the function start, if \( a \) is greater than 4, control flow is passed to label $LN1@f, where printf() with argument 'something unknown' is called.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
But if the value of $a$ is less or equals to 4, then it gets multiplied by 4 and added with the $\$LN11@f$ table address. That is how an address inside the table is constructed, pointing exactly to the element we need. For example, let's say $a$ is equal to 2. $2 \times 4 = 8$ (all table elements are addresses in a 32-bit process and that is why all elements are 4 bytes wide). The address of the $\$LN11@f$ table + 8 is the table element where the $\$LN4@f$ label is stored. JMP fetches the $\$LN4@f$ address from the table and jumps to it.

This table is sometimes called \textit{jumptable} or \textit{branch table}.\footnote{The whole method was once called \textit{computed GOTO} in early versions of Fortran: \url{wikipedia}. Not quite relevant these days, but what a term!}

Then the corresponding \texttt{printf()} is called with argument ‘two’. Literally, the \texttt{jmp DWORD PTR $LN11@f[ecx*4]} instruction implies \textit{jump to the DWORD that is stored at address $\$LN11@f + ecx \times 4$}.

\texttt{npad (.1.7 on page 1011)} is an assembly language macro that align the next label so that it will be stored at an address aligned on a 4 bytes (or 16 bytes) boundary. This is very suitable for the processor since it is able to fetch 32-bit values from memory through the memory bus, cache memory, etc., in a more effective way if it is aligned.
Let's try this example in OllyDbg. The input value of the function (2) is loaded into EAX:

Figure 1.51: OllyDbg: function’s input value is loaded in EAX
The input value is checked, is it bigger than 4? If not, the “default” jump is not taken:

Figure 1.52: OllyDbg: 2 is no bigger than 4: no jump is taken
Here we see a jumptable:

Figure 1.53: OllyDbg: calculating destination address using jumptable

Here we’ve clicked “Follow in Dump” → “Address constant”, so now we see the jumptable in the data window. These are 5 32-bit values\(^{96}\). ECX is now 2, so the third element (can be indexed as 2\(^{97}\)) of the table is to be used. It’s also possible to click “Follow in Dump” → “Memory address” and OllyDbg will show the element addressed by the JMP instruction. That’s 0x010B103A.

\(^{96}\)They are underlined by OllyDbg because these are also FIXUPs: 6.5.2 on page 759, we are going to come back to them later

\(^{97}\)About indexing, see also: 3.20.3 on page 601

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
After the jump we are at 0x010B103A: the code printing “two” will now be executed:

Non-optimizing GCC

Let’s see what GCC 4.4.1 generates:

```assembly
Listing 1.158: GCC 4.4.1

public f
f proc near ; CODE XREF: main+10
var_18 = dword ptr -18
arg_0 = dword ptr 8

    push    ebp
    mov     ebp, esp
    sub     esp, 18
    cmp [ebp+arg_0], 4
    ja      short loc_8048444
    mov     eax, [ebp+arg_0]
    shl     eax, 2
    mov     eax, ds:off_804855C[eax]
    jmp     eax
loc_80483FE: ; DATA XREF: .rodata:off 804855C
    mov     [esp+18h+var_18], offset aZero ; "zero"
    call    _puts
    jmp     short loc_8048450
loc_804840C: ; DATA XREF: .rodata:08048560
    mov     [esp+18h+var_18], offset aOne ; "one"
    call    _puts
    jmp     short loc_8048450
loc_804841A: ; DATA XREF: .rodata:08048564
    mov     [esp+18h+var_18], offset aTwo ; "two"
    call    _puts
    jmp     short loc_8048450
loc_8048428: ; DATA XREF: .rodata:08048568
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
It is almost the same, with a little nuance: argument arg_0 is multiplied by 4 by shifting it to left by 2 bits (it is almost the same as multiplication by 4) (1.24.2 on page 219). Then the address of the label is taken from the off_804855C array, stored in EAX, and then JMP EAX does the actual jump.

ARM: Optimizing Keil 6/2013 (ARM mode)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This code makes use of the ARM mode feature in which all instructions have a fixed size of 4 bytes.

Let’s keep in mind that the maximum value for \(a\) is 4 and any greater value will cause «something unknown» string to be printed.

The first CMP \(R0, #5\) instruction compares the input value of \(a\) with 5.

The next ADDCC \(PC, PC, R0, LSL#2\) instruction is being executed only if \(R0 < 5\) (\(CC=Carry\_clear/\_Less\_than\)). Consequently, if ADDCC does not trigger (it is a \(R0 \geq 5\) case), a jump to \(default\_case\) label will occur.

But if \(R0 < 5\) and ADDCC triggers, the following is to be happen:

The value in \(R0\) is multiplied by 4. In fact, \(LSL#2\) at the instruction’s suffix stands for “shift left by 2 bits”. But as we will see later (1.24.2 on page 219) in section “Shifts”, shift left by 2 bits is equivalent to multiplying by 4.

Then we add \(R0 \times 4\) to the current value in \(PC\), thus jumping to one of the B (Branch) instructions located below.

At the moment of the execution of ADDCC, the value in \(PC\) is 8 bytes ahead (0x180) than the address at which the ADDCC instruction is located (0x178), or, in other words, 2 instructions ahead.

This is how the pipeline in ARM processors works: when ADDCC is executed, the processor at the moment is beginning to process the instruction after the next one, so that is why \(PC\) points there. This has to be memorized.

If \(a = 0\), then is to be added to the value in \(PC\), and the actual value of the \(PC\) will be written into \(PC\) (which is 8 bytes ahead) and a jump to the label \(loc\_180\) will happen, which is 8 bytes ahead of the point where the ADDCC instruction is.

If \(a = 1\), then \(PC + 8 + a \times 4 = PC + 8 + 1 \times 4 = PC + 12 = 0x184\) will be written to \(PC\), which is the address of the \(loc\_184\) label.

With every 1 added to \(a\), the resulting \(PC\) is increased by 4.

4 is the instruction length in ARM mode and also, the length of each B instruction, of which there are 5 in row.

Each of these five B instructions passes control further, to what was programmed in the \(switch()\).

Pointer loading of the corresponding string occurs there, etc.
One cannot be sure that all instructions in Thumb and Thumb-2 modes has the same size. It can even be said that in these modes the instructions have variable lengths, just like in x86.

So there is a special table added that contains information about how much cases are there (not including default-case), and an offset for each with a label to which control must be passed in the corresponding
A special function is present here in order to deal with the table and pass control, named __ARM_common_switch8_thumb. It starts with BX PC, whose function is to switch the processor to ARM-mode. Then you see the function for table processing.

It is too advanced to describe it here now, so let’s omit it.

It is interesting to note that the function uses the LR register as a pointer to the table.

Indeed, after calling of this function, LR contains the address after BL __ARM_common_switch8_thumb instruction, where the table starts.

It is also worth noting that the code is generated as a separate function in order to reuse it, so the compiler doesn’t generate the same code for every switch() statement.

IDA successfully perceived it as a service function and a table, and added comments to the labels like jumptable 000000FA case 0.

MIPS

Listing 1.161: Optimizing GCC 4.4.5 (IDA)

f:
  lui $gp, (__gnu_local_gp >> 16)
  ; jump to loc_24 if input value is lesser than 5:
  sltiu $v0, $a0, 5
  bnez $v0, loc_24
  la $gp, (__gnu_local_gp & 0xFFFF) ; branch delay slot
  ; input value is greater or equal to 5.
  ; print "something unknown" and finish:
  lui $a0, ($LC5 >> 16) # "something unknown"
  lw $t9, (puts & 0xFFFF)(gp)
  or $at, $zero ; NOP
  jr $t9
  la $a0, ($LC5 & 0xFFFF) # "something unknown" ; branch delay slot

loc_24:
  # CODE XREF: f+8
  ; load address of jumptable
  ; LA is pseudoinstruction, LUI and ADDIU pair are there in fact:
  la $v0, off_120
  ; multiply input value by 4:
  sll $a0, 2
  ; sum up multiplied value and jumptable address:
  addu $a0, $v0, $a0
  ; load element from jumptable:
  lw $v0, 0($a0)
  or $at, $zero ; NOP
  jr $v0
  or $at, $zero ; branch delay slot, NOP

sub_44:
  # CODE XREF: .rodata:000012C
  ; print "three" and finish
  lui $a0, ($LC3 >> 16) # "three"
  lw $t9, (puts & 0xFFFF)(gp)
  or $at, $zero ; NOP
  jr $t9
  la $a0, ($LC3 & 0xFFFF) # "three" ; branch delay slot

sub_58:
  # CODE XREF: .rodata:0000130
  ; print "four" and finish
  lui $a0, ($LC4 >> 16) # "four"
  lw $t9, (puts & 0xFFFF)(gp)
  or $at, $zero ; NOP
  jr $t9
  la $a0, ($LC4 & 0xFFFF) # "four" ; branch delay slot

sub_6C:
  # CODE XREF: .rodata:off_120
  ; print "zero" and finish
The new instruction for us is SLTIU (“Set on Less Than Immediate Unsigned”).
This is the same as SLTU (“Set on Less Than Unsigned”), but “I” stands for “immediate”, i.e., a number
has to be specified in the instruction itself.
BNEZ is “Branch if Not Equal to Zero”.
Code is very close to the other ISAs. SLL (“Shift Word Left Logical”) does multiplication by 4.
MIPS is a 32-bit CPU after all, so all addresses in the jumptable are 32-bit ones.

**Conclusion**

Rough skeleton of switch():

```
MOV REG, input
CMP REG, 4 ; maximal number of cases
JA default
SLL REG, 2 ; find element in table. shift for 3 bits in x64.
MOV REG, jump_table[REG]
JMP REG

case1:
; do something
    JMP exit

case2:
; do something
    JMP exit

case3:
; do something
    JMP exit

case4:
; do something
    JMP exit

case5:
; do something
    JMP exit

default:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The jump to the address in the jump table may also be implemented using this instruction:  
JMP jump_table[REG*4]. Or JMP jump_table[REG*8] in x64.

A jumtable is just array of pointers, like the one described later: 1.26.5 on page 287.

### 1.21.3 When there are several case statements in one block

Here is a very widespread construction: several case statements for a single block:

```c
#include <stdio.h>

void f(int a)
{
    switch (a)
    {
    case 1:
    case 2:
    case 7:
    case 10:
        printf("1, 2, 7, 10\n");
        break;
    case 3:
    case 4:
    case 5:
    case 6:
        printf("3, 4, 5\n");
        break;
    case 8:
    case 9:
    case 20:
    case 21:
        printf("8, 9, 21\n");
        break;
    case 22:
        printf("22\n");
        break;
    default:
        printf("default\n");
        break;
    }
}

int main()
{
    f(4);
}
```

It’s too wasteful to generate a block for each possible case, so what is usually done is to generate each block plus some kind of dispatcher.
We see two tables here: the first table ($LN10@f$) is an index table, and the second one ($LN11@f$) is an array of pointers to blocks.

First, the input value is used as an index in the index table (line 13).

Here is a short legend for the values in the table: 0 is the first case block (for values 1, 2, 7, 10), 1 is the second one (for values 3, 4, 5), 2 is the third one (for values 8, 9, 21), 3 is the fourth one (for value 22), 4 is for the default block.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There we get an index for the second table of code pointers and we jump to it (line 14).

What is also worth noting is that there is no case for input value 0.

That’s why we see the DEC instruction at line 10, and the table starts at \( a = 1 \), because there is no need to allocate a table element for \( a = 0 \).

This is a very widespread pattern.

So why is this economical? Why isn’t it possible to make it as before (1.21.2 on page 174), just with one table consisting of block pointers? The reason is that the elements in index table are 8-bit, hence it’s all more compact.

**GCC**

GCC does the job in the way we already discussed (1.21.2 on page 174), using just one table of pointers.

**ARM64: Optimizing GCC 4.9.1**

There is no code to be triggered if the input value is 0, so GCC tries to make the jump table more compact and so it starts at 1 as an input value.

GCC 4.9.1 for ARM64 uses an even cleverer trick. It’s able to encode all offsets as 8-bit bytes.

Let’s recall that all ARM64 instructions have a size of 4 bytes.

GCC is uses the fact that all offsets in my tiny example are in close proximity to each other. So the jump table consisting of single bytes.

**Listing 1.164: Optimizing GCC 4.9.1 ARM64**

```assembly
f14:
  ; input value in W0
  sub   w0, w0, #1
  cmp   w0, 21
  ; branch if less or equal (unsigned):
  bls   .L9
.L2:
  ; print "default":
  adrp  x0, .LC4
  add   x0, x0, :lo12:.LC4
  b     puts
.L9:
  ; load jumptable address to X1:
  adrp  x1, .L4
  add   x1, x1, :lo12:.L4
  W0=input_value-1
  ; load byte from the table:
  ldrb  w0, [x1,w0,uxtw]
  ; load address of the Lrtx label:
  adr   x1, .Lrtx4
  ; multiply table element by 4 (by shifting 2 bits left) and add (or subtract) to the address of Lrtx:
  add   x0, x1, w0, sxtb #2
  ; jump to the calculated address:
  br    x0
  ; this label is pointing in code (text) segment:
.Lrtx4:
  .section .rodata
  ; everything after ".section" statement is allocated in the read-only data (rodata) segment:
.L4:
  .byte   (.L3 - .Lrtx4) / 4 ; case 1
  .byte   (.L3 - .Lrtx4) / 4 ; case 2
  .byte   (.L5 - .Lrtx4) / 4 ; case 3
  .byte   (.L5 - .Lrtx4) / 4 ; case 4
  .byte   (.L5 - .Lrtx4) / 4 ; case 5
  .byte   (.L5 - .Lrtx4) / 4 ; case 6
  .byte   (.L3 - .Lrtx4) / 4 ; case 7
  .byte   (.L6 - .Lrtx4) / 4 ; case 8
  .byte   (.L6 - .Lrtx4) / 4 ; case 9
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let's compile this example to object file and open it in IDA. Here is the jump table:

```
Listing 1.165: jumptable in IDA

    .text
    ; everything after ".text" statement is allocated in the code (text) segment:
    .L7:
    ; print "22"
    adrp  x0, .LC3
    add  x0, x0, :lo12:.LC3
    b    puts

    .L6:
    ; print "8, 9, 21"
    adrp  x0, .LC2
    add  x0, x0, :lo12:.LC2
    b    puts

    .L5:
    ; print "3, 4, 5"
    adrp  x0, .LC1
    add  x0, x0, :lo12:.LC1
    b    puts

    .L3:
    ; print "1, 2, 7, 10"
    adrp  x0, .LC0
    add  x0, x0, :lo12:.LC0
    b    puts

    .LC0: .string "1, 2, 7, 10"
    .LC1: .string "3, 4, 5"
    .LC2: .string "8, 9, 21"
    .LC3: .string "22"
    .LC4: .string "default"
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
So in case of 1, 9 is to be multiplied by 4 and added to the address of Lrtx4 label.

In case of 22, 0 is to be multiplied by 4, resulting in 0.

Right after the Lrtx4 label is the L7 label, where you can find the code that prints “22”.

There is no jump table in the code segment, it’s allocated in a separate .rodata section (there is no special necessity to place it in the code section).

There are also negative bytes (0xF7), they are used for jumping back to the code that prints the “default” string (at .L2).

### 1.21.4 Fall-through

Another popular usage of switch() operator is so-called “fallthrough”. Here is simple example:

```c
bool is_whitespace(char c) {
    switch (c) {
        case ' ': // fallthrough
        case '\t': // fallthrough
        case '\r': // fallthrough
        case '\n':
            return true;
        default: // not whitespace
            return false;
    }
}
```

Slightly harder, from Linux kernel:

```c
char nco1, nco2;

void f(int if_freq_khz) {
    switch (if_freq_khz) {
        default:
            printf("IF=%d KHz is not supported, 3250 assumed\n", if_freq_khz);
        /* fallthrough */
        case 3250: /* 3.25Mhz */
            nco1 = 0x34;
            nco2 = 0x00;
            break;
        case 3500: /* 3.50Mhz */
            nco1 = 0x38;
            nco2 = 0x00;
            break;
        case 4000: /* 4.00Mhz */
            nco1 = 0x40;
            nco2 = 0x00;
            break;
        case 5000: /* 5.00Mhz */
            nco1 = 0x50;
            nco2 = 0x00;
            break;
        case 5380: /* 5.38Mhz */
            nco1 = 0x56;
            nco2 = 0x14;
            break;
    }
}
```

99 Copypasted from https://github.com/azonalon/prgraas/blob/master/progllib/lecture_examples/is_whitespace.c

100 Copypasted from https://github.com/torvalds/linux/blob/master/drivers/media/dvb-frontends/lgdt3306a.c

(For statistics collecting purposes) if you’ve read this far, please click [here](https://github.com/azonalon/prgraas/blob/master/progllib/lecture_examples/is_whitespace.c). Thanks!
We can get to .L5 label if there is number 3250 at function’s input. But we can get to this label from the other side: we see that there are no jumps between printf() call and .L5 label.

Now we can understand why switch() statement is sometimes a source of bugs: one forgotten break will transform your switch() statement into fallthrough one, and several blocks will be executed instead of single one.

### 1.21.5 Exercises

#### Exercise#1

It’s possible to rework the C example in 1.21.2 on page 168 in such way that the compiler can produce even smaller code, but will work just the same. Try to achieve it.
1.22 Loops

1.22.1 Simple example

x86

There is a special LOOP instruction in x86 instruction set for checking the value in register ECX and if it is not 0, to decrement ECX and pass control flow to the label in the LOOP operand. Probably this instruction is not very convenient, and there are no any modern compilers which emit it automatically. So, if you see this instruction somewhere in code, it is most likely that this is a manually written piece of assembly code.

In C/C++ loops are usually constructed using for(), while() or do/while() statements.

Let's start with for().

This statement defines loop initialization (set loop counter to initial value), loop condition (is the counter bigger than a limit?), what is performed at each iteration (increment/decrement) and of course loop body.

```c
for (initialization; condition; at each iteration)
{
    loop_body;
}
```

The generated code is consisting of four parts as well.

Let's start with a simple example:

```c
#include <stdio.h>

void printing_function(int i)
{
    printf("f(%d)\n", i);
};

int main()
{
    int i;
    for (i=2; i<10; i++)
        printing_function(i);
    return 0;
};
```

The result (MSVC 2010):

```
Listing 1.167: MSVC 2010

_i$ = -4
main PROC
    push ebp
    mov ebp, esp
    push ecx
    mov DWORD PTR _i$[ebp], 2 ; loop initialization
    jmp SHORT $LN3@main
$LN2@main:
    mov eax, DWORD PTR _i$[ebp] ; here is what we do after each iteration:
    add eax, 1 ; add 1 to (i) value
    mov DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp DWORD PTR _i$[ebp], 10 ; this condition is checked before each iteration
    jge SHORT $LN1@main ; if (i) is biggest or equals to 10, lets finish loop
    mov ecx, DWORD PTR _i$[ebp] ; loop body: call printing_function(i)
    push ecx
    call _printing_function
    add esp, 4
    jmp SHORT $LN2@main ; jump to loop begin
$LN1@main:
    ; loop end
    xor eax, eax
    mov esp, ebp
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As we see, nothing special. GCC 4.4.1 emits almost the same code, with one subtle difference:

Listing 1.168: GCC 4.4.1

```
main proc near
var_20 = dword ptr -20h
var_4  = dword ptr -4

push    ebp
mov     ebp, esp
and     esp, 0FFFFFFF0h
sub     esp, 20h
mov     [esp+20h+var_4], 2 ; (i) initializing
jmp     short loc_8048476

loc_8048465:
  mov     eax, [esp+20h+var_4]
  mov     [esp+20h+var_20], eax
  call    printing_function
  add     [esp+20h+var_4], 1 ; (i) increment

loc_8048476:
  cmp     [esp+20h+var_4], 9
  jle     short loc_8048465 ; if i<=9, continue loop
  mov     eax, 0
  leave
  ret

_main    ENDP
```

Now let's see what we get with optimization turned on (/Ox):

Listing 1.169: Optimizing MSVC

```
_main    PROC
    push    esi
    mov     esi, 2
$LL3@main:
    push    esi
    call    _printing_function
    inc     esi
    add     esp, 4
    cmp     esi, 10 ; 0000000ah
    jl      SHORT $LL3@main
    xor     eax, eax
    pop     esi
    ret

_main    ENDP
```

What happens here is that space for the i variable is not allocated in the local stack anymore, but uses an individual register for it, ESI. This is possible in such small functions where there aren't many local variables.

One very important thing is that the f() function must not change the value in ESI. Our compiler is sure here. And if the compiler decides to use the ESI register in f() too, its value would have to be saved at the function's prologue and restored at the function's epilogue, almost like in our listing: please note PUSH ESI/POP ESI at the function start and end.

Let's try GCC 4.4.1 with maximal optimization turned on (-O3 option):

Listing 1.170: Optimizing GCC 4.4.1

```
main proc near
var_10  = dword ptr -10h
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
push ebp
mov ebp, esp
and esp, 0FFFFFFFF0h
sub esp, 10h
mov [esp+10h+var_10], 2
call printing_function
mov [esp+10h+var_10], 3
call printing_function
mov [esp+10h+var_10], 4
call printing_function
mov [esp+10h+var_10], 5
call printing_function
mov [esp+10h+var_10], 6
call printing_function
mov [esp+10h+var_10], 7
call printing_function
mov [esp+10h+var_10], 8
call printing_function
mov [esp+10h+var_10], 9
call printing_function
xor eax, eax
leave
retn

main endp

Huh, GCC just unwound our loop.

Loop unwinding has an advantage in the cases when there aren’t much iterations and we could cut some execution time by removing all loop support instructions. On the other side, the resulting code is obviously larger.

Big unrolled loops are not recommended in modern times, because bigger functions may require bigger cache footprint\(^{101}\).

OK, let’s increase the maximum value of the \(i\) variable to 100 and try again. GCC does:

```plaintext
Listing 1.171: GCC

public main
main proc near
var_20 = dword ptr -20h

push ebp
mov ebp, esp
and esp, 0FFFFFFFF0h
push ebx
mov ebx, 2 ; i=2
sub esp, 1Ch

; aligning label loc_80484D0 (loop body begin) by 16-byte border:
nop

loc_80484D0:
; pass (i) as first argument to printing_function():
mov [esp+20h+var_20], ebx
add ebx, 1 ; i++
call printing_function
cmp ebx, 64h ; i==100?
jnz short loc_80484D0 ; if not, continue
add esp, 1Ch
xor eax, eax ; return 0
pop ebx
mov esp, ebp
pop ebp
retn

main endp
```

\(^{101}\)A very good article about it: [Ulrich Drepper, *What Every Programmer Should Know About Memory*, (2007)]\(^{102}\). Another recommendations about loop unrolling from Intel are here: [Intel® 64 and IA-32 Architectures Optimization Reference Manual, (2014)3.4.1.7].
It is quite similar to what MSVC 2010 with optimization (/Ox) produce, with the exception that the EBX register is allocated for the \textit{i} variable.

GCC is sure this register will not be modified inside of the \textit{f()} function, and if it will, it will be saved at the function prologue and restored at epilogue, just like here in the \textit{main()} function.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s compile our example in MSVC 2010 with /Ox and /Ob0 options and load it into OllyDbg.

It seems that OllyDbg is able to detect simple loops and show them in square brackets, for convenience:

![CPU - main thread, module loops_2]

Figure 1.55: OllyDbg: main() begin

By tracing (F8 — step over) we see ESI incrementing. Here, for instance, $ESI = i = 6$:

![CPU - main thread, module loops_2]

Figure 1.56: OllyDbg: loop body just executed with $i = 6$

9 is the last loop value. That’s why JL is not triggering after the increment, and the function will finish:
As we might see, it is not very convenient to trace manually in the debugger. That’s a reason we will try tracer.

We open compiled example in IDA, find the address of the instruction PUSH ESI (passing the sole argument to f()), which is 0x401026 for this case and we run the tracer:

```
tracer.exe -l:loops_2.exe bpx=loops_2.exe!0x00401026
```

BPX just sets a breakpoint at the address and tracer will then print the state of the registers.

In the tracer.log, this is what we see:

```
PID=12884|New process loops_2.exe

```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We see how the value of ESI register changes from 2 to 9.

Even more than that, the tracer can collect register values for all addresses within the function. This is called trace there. Every instruction gets traced, all interesting register values are recorded.

Then, an IDA.idc-script is generated, that adds comments. So, in the IDA we’ve learned that the main() function address is 0x00401020 and we run:

```
tracer.exe -l:loops_2.exe bpf=loops_2.exe!0x00401020,trace:cc
```

BPF stands for set breakpoint on function.

As a result, we get the loops_2.exe.idc and loops_2.exe_clear.idc scripts.
We load loops_2.exe.idc into IDA and see:

Figure 1.58: IDA with .idc-script loaded

We see that ESI can be from 2 to 9 at the start of the loop body, but from 3 to 0xA (10) after the increment. We can also see that main() is finishing with 0 in EAX.

tracer also generates loops_2.exe.txt, that contains information about how many times each instruction has been executed and register values:

Listing 1.172: loops_2.exe.txt

We can use grep here.

ARM

Non-optimizing Keil 6/2013 (ARM mode)
Iteration counter $i$ is to be stored in the R4 register. The MOV R4, #2 instruction just initializes $i$. The MOV R0, R4 and BL printing_function instructions compose the body of the loop, the first instruction preparing the argument for $f()$ function and the second calling the function. The ADD R4, R4, #1 instruction just adds 1 to the $i$ variable at each iteration. CMP R4, #0xA compares $i$ with 0xA (10). The next instruction BLT (Branch Less Than) jumps if $i$ is less than 10. Otherwise, 0 is to be written into R0 (since our function returns 0) and function execution finishes.

**Optimizing Keil 6/2013 (Thumb mode)**

```assembly
_MAIN
  PUSH {R4,LR}
  MOVS R4, #2
LOC_132 ; CODE XREF: _main+E
  MOVS R0, R4
  BL printing_function
  ADDS R4, R4, #1
  CMP R4, #0xA
  BLT loc_132
  MOVS R0, #0
  POP {R4,PC}
```

Practically the same.

**Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)**

```assembly
_MAIN
  PUSH {R4,R7,LR}
  MOVW R4, #0x1124 ; "%d\n"
  MOVS R1, #2
  MOV.T.W R4, #0
  ADD R7, SP, #4
  ADD R4, PC
  MOV R0, R4
  BLX printf
  MOV R0, R4
  MOVS R1, #3
  BLX printf
  MOV R0, R4
  MOVS R1, #4
  BLX printf
  MOV R0, R4
  MOVS R1, #5
  BLX printf
  MOV R0, R4
  MOVS R1, #6
  BLX printf
  MOV R0, R4
  MOVS R1, #7
  BLX printf
  MOV R0, R4
  MOVS R1, #8
  BLX printf
  MOV R0, R4
  MOVS R1, #9
  BLX printf
  MOV R0, #0
  POP {R4,R7,PC}
```

In fact, this was in my $f()$ function:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
So, LLVM not just unrolled the loop, but also inlined my very simple function `f()`, and inserted its body 8 times instead of calling it.

This is possible when the function is so simple (like mine) and when it is not called too much (like here).
str w0, [x29,28]
; load address of the "f%d\n" string
adrp x0, .LC0
add x0, x0, :lo12:.LC0
; reload input value from the local stack to W1 register:
ldr w1, [x29,28]
; call printf()
bl printf
; restore FP and LR values:
ldp x29, x30, [sp], 32
ret

main:
; save FP and LR in the local stack:
stp x29, x30, [sp, -32]!
; set up stack frame:
add x29, sp, 0
; initialize counter
mov w0, 2
; store it to the place allocated for it in the local stack:
str w0, [x29,28]
; skip loop body and jump to the loop condition check instructions:
b .L3
.L4:
; load counter value to W0.
; it will be the first argument of printing_function():
ldr w0, [x29,28]
; call printing_function():
bl printing_function
; increment counter value:
add w0, w0, 1
str w0, [x29,28]
.L3:
; loop condition check.
; load counter value:
ldr w0, [x29,28]
; is it 9?
cmp w0, 9
; less or equal? then jump to loop body begin:
; do nothing otherwise.
ble .L4
; return 0
mov w0, 0
; restore FP and LR values:
ldp x29, x30, [sp], 32
ret

MIPS

Listing 1.175: Non-optimizing GCC 4.4.5 (IDA)

main:
; IDA is not aware of variable names in local stack
; We gave them names manually:
i = -0x10
saved_FP = -8
saved_RA = -4

; function prologue:
addiu $sp, -0x28
sw $ra, 0x28+saved_RA($sp)
sw $fp, 0x28+saved_FP($sp)
mv $fp, $sp
; initialize counter at 2 and store this value in local stack
li $v0, 2
sw $v0, 0x28+i($fp)
; pseudoinstruction. "BEQ $ZERO, $ZERO, loc_9C" there in fact:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The instruction that’s new to us is B. It is actually the pseudo instruction (BEQ).

One more thing

In the generated code we can see: after initializing i, the body of the loop is not to be executed, as the condition for i is checked first, and only after that loop body can be executed. And that is correct.

Because, if the loop condition is not met at the beginning, the body of the loop must not be executed. This is possible in the following case:

```c
for (i=0; i<total_entries_to_process; i++)
    loop_body;
```

If total_entries_to_process is 0, the body of the loop must not be executed at all.

This is why the condition checked before the execution.

However, an optimizing compiler may swap the condition check and loop body, if it sure that the situation described here is not possible (like in the case of our very simple example and using compilers like Keil, Xcode (LLVM), MSVC in optimization mode).

1.22.2 Memory blocks copying routine

Real-world memory copy routines may copy 4 or 8 bytes at each iteration, use SIMD\textsuperscript{103}, vectorization, etc. But for the sake of simplicity, this example is the simplest possible.

```c
#include <stdio.h>

void my_memcpy(unsigned char* dst, unsigned char* src, size_t cnt)
{
    size_t i;
    for (i=0; i<cnt; i++)
        dst[i]=src[i];
}
```

\textsuperscript{103}Single Instruction, Multiple Data

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.176: GCC 4.9 x64 optimized for size (-Os)

```assembly
my_memcpy:
    ; RDI = destination address
    ; RSI = source address
    ; RDX = size of block

    ; initialize counter (i) at 0
    xor    eax, eax
.L2:
    ; all bytes copied? exit then:
    cmp    rax, rdx
    je     .L5
    ; load byte at RSI+i:
    mov    cl, BYTE PTR [rsi+rax]
    ; store byte at RDI+i:
    mov    BYTE PTR [rdi+rax], cl
    inc    rax ; i++
    jmp    .L2
.L5:
    ret
```

Listing 1.177: GCC 4.9 ARM64 optimized for size (-Os)

```assembly
my_memcpy:
    ; X0 = destination address
    ; X1 = source address
    ; X2 = size of block

    ; initialize counter (i) at 0
    mov    x3, 0
.L2:
    ; all bytes copied? exit then:
    cmp    x3, x2
    beq    .L5
    ; load byte at X1+i:
    ldrb   w4, [x1,x3]
    ; store byte at X0+i:
    strb   w4, [x0,x3]
    add    x3, x3, 1 ; i++
    b      .L2
.L5:
    ret
```

Listing 1.178: Optimizing Keil 6/2013 (Thumb mode)

```assembly
my_memcpy PROC
    ; R0 = destination address
    ; R1 = source address
    ; R2 = size of block

    ; initialize counter (i) at 0
    MOVVS  r3,#0
    ; condition checked at the end of function, so jump there:
    B      |L0.12|
.L0.6|
    ; load byte at R1+i:
    LDRB   r4,[r1,r3]
    ; store byte at R0+i:
    STRB   r4,[r0,r3]
    ; i++
    ADDS   r3,r3,#1
.L0.12|
    ; i<size?
    CMP    r3,r2
    ; jump to the loop begin if its so:
    BCC    |L0.6|
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
ARM in ARM mode

Keil in ARM mode takes full advantage of conditional suffixes:

```
POP {r4,pc}
ENDP
```

Listing 1.179: Optimizing Keil 6/2013 (ARM mode)

```
my_memcpy PROC
; R0 = destination address
; R1 = source address
; R2 = size of block

; initialize counter (i) at 0
MOV r3,#0
|L0.4|
; all bytes copied?
CMP r3,r2
; the following block is executed only if less than condition,
; i.e., if R2<R3 or i<size.
; load byte at R1+i:
LDRBCC r12,[r1,r3]
; store byte at R0+i:
STRBCC r12,[r0,r3]
; i++
ADDCC r3,r3,#1
; the last instruction of the conditional block.
; jump to loop begin if i<size
; do nothing otherwise (i.e., if i>=size)
BCC |L0.4|
; return
BX lr
ENDP
```

That’s why there is only one branch instruction instead of 2.

MIPS

Listing 1.180: GCC 4.4.5 optimized for size (-Os) (IDA)

```
my_memcpy:
; jump to loop check part:
   b loc_14
; initialize counter (i) at 0
; it will always reside in $v0:
   move $v0, $zero ; branch delay slot
loc_8:       # CODE XREF: my_memcpy+1C
; load byte as unsigned at address in $t0 to $v1:
   lbu $v1, 0($t0)
; increment counter (i):
   addiu $v0, 1
; store byte at $a3
   sb $v1, 0($a3)
loc_14:      # CODE XREF: my_memcpy
; check if counter (i) in $v0 is still less then 3rd function argument ("cnt" in $a2):
   sltu $v1, $v0, $a2
; form address of byte in source block:
   addu $t0, $a1, $v0
; $t0 = $a1+$v0 = src+i
; jump to loop body if counter sill less then "cnt":
   bnez $v1, loc_8
; form address of byte in destination block ($a3 = $a0+$v0 = dst+i):
   addu $a3, $a0, $v0 ; branch delay slot
; finish if BNEZ wasnt triggered:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here we have two new instructions: LBU ("Load Byte Unsigned") and SB ("Store Byte").

Just like in ARM, all MIPS registers are 32-bit wide, there are no byte-wide parts like in x86.

So when dealing with single bytes, we have to allocate whole 32-bit registers for them.
LBU loads a byte and clears all other bits ("Unsigned").
On the other hand, LB ("Load Byte") instruction sign-extends the loaded byte to a 32-bit value.
SB just writes a byte from lowest 8 bits of register to memory.

**Vectorization**

Optimizing GCC can do much more on this example: [1.36.1 on page 417](#).

### 1.22.3 Condition check

It’s important to keep in mind that in `for()` construct, condition is checked not at the end, but at the beginning, before execution of loop body. But often, it’s more convenient for compiler to check it at the end, after body. Sometimes, additional check can be appended at the beginning.

For example:

```c
#include <stdio.h>

void f(int start, int finish)
{
    for (; start<finish; start++)
        printf("%d\n", start);
}
```

Optimizing GCC 5.4.0 x64:

```c
f:
; check condition (1):
    cmp    edi, esi
    jge    .L9
    push   rbp
    push   rbx
    mov    ebp, esi
    mov    ebx, edi
    sub    rsp, 8
.L5:
    mov    edx, ebx
    xor    eax, eax
    mov    esi, OFFSET FLAT:.LC0 ; "%d\n"
    mov    edi, 1
    add    ebx, 1
    call   __printf_chk
; check condition (2):
    cmp    ebp, ebx
    jne    .L5
    add    rsp, 8
    pop    rbx
    pop    rbp
.L9:
    rep    ret
```

We see two checks.

Hex-Rays (at least version 2.2.0) decompiles this as:

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
In this case, \texttt{do/while()} can be replaced by \texttt{for()} without any doubt, and the first check can be removed.

\section*{1.22.4 Conclusion}

Rough skeleton of loop from 2 to 9 inclusive:

\begin{verbatim}
Listing 1.181: x86
  mov [counter], 2 ; initialization
  jmp check
  ; loop body
  ; do something here
  ; use counter variable in local stack
  add [counter], 1 ; increment
  ; check:
  cmp [counter], 9
  jle body
\end{verbatim}

The increment operation may be represented as 3 instructions in non-optimized code:

\begin{verbatim}
Listing 1.182: x86
  MOV [counter], 2 ; initialization
  JMP check
  ; loop body
  ; do something here
  ; use counter variable in local stack
  MOV REG, [counter] ; increment
  INC REG
  MOV [counter], REG
  ; check:
  CMP [counter], 9
  JLE body
\end{verbatim}

If the body of the loop is short, a whole register can be dedicated to the counter variable:

\begin{verbatim}
Listing 1.183: x86
  MOV EBX, 2 ; initialization
  JMP check
  ; loop body
  ; do something here
  ; use counter in EBX, but do not modify it!
  INC EBX ; increment
  ; check:
  CMP EBX, 9
  JLE body
\end{verbatim}
Some parts of the loop may be generated by compiler in different order:

Listing 1.184: x86

```
MOV [counter], 2 ; initialization
JMP label_check
label increment:
  ADD [counter], 1 ; increment
label_check:
  CMP [counter], 10
  JGE exit
  ; loop body
  ; do something here
  ; use counter variable in local stack
  JMP label_increment
exit:
```

Usually the condition is checked before loop body, but the compiler may rearrange it in a way that the condition is checked after loop body.

This is done when the compiler is sure that the condition is always true on the first iteration, so the body of the loop is to be executed at least once:

Listing 1.185: x86

```
MOV REG, 2 ; initialization
body:
  ; loop body
  ; do something here
  ; use counter in REG, but do not modify it!
  INC REG ; increment
  CMP REG, 10
  JL body
```

Using the LOOP instruction. This is rare, compilers are not using it. When you see it, it’s a sign that this piece of code is hand-written:

Listing 1.186: x86

```
; count from 10 to 1
MOV ECX, 10
body:
  ; loop body
  ; do something here
  ; use counter in ECX, but do not modify it!
  LOOP body
```

ARM.

The R4 register is dedicated to counter variable in this example:

Listing 1.187: ARM

```
MOV R4, 2 ; initialization
B check
body:
  ; loop body
  ; do something here
  ; use counter in R4, but do not modify it!
  ADD R4,R4, #1 ; increment
check:
  CMP R4, #10
  BLT body
```

### 1.22.5 Exercises

- [http://challenges.re/54](http://challenges.re/54)
- [http://challenges.re/55](http://challenges.re/55)
1.23 More about strings

1.23.1 strlen()

Let's talk about loops one more time. Often, the `strlen()` function is implemented using a `while()` statement. Here is how it is done in the MSVC standard libraries:

```c
int my_strlen (const char * str)
{
    const char *eos = str;
    while( *eos++ ) ;
    return( eos - str - 1 );
}

int main()
{
    // test
    return my_strlen("hello");
}
```

**x86**

**Non-optimizing MSVC**

Let's compile:

```assembly
_eos$ = -4       ; size = 4
_str$ = 8        ; size = 4
__strlen PROC
    push   ebp
    mov    ebp, esp
    push   ecx
    mov    eax, DWORD PTR _str$[ebp] ; place pointer to string from "str"
    mov    DWORD PTR _eos$[ebp], eax ; place it to local variable "eos"
$LN2@strlen_:
    mov    ecx, DWORD PTR _eos$[ebp] ; ECX=eos
        ; take 8-bit byte from address in ECX and place it as 32-bit value to EDX with sign extension
    movsx  edx, BYTE PTR [ecx]
    mov    eax, DWORD PTR _eos$[ebp] ; EAX=eos
    add    eax, 1                      ; increment EAX
    mov    DWORD PTR _eos$[ebp], eax ; place EAX back to "eos"
    test   edx, edx                    ; EDX is zero?
    je     SHORT $LN1@strlen_          ; yes, then finish loop
    jmp    SHORT $LN2@strlen_          ; continue loop

$LN1@strlen_:
    ; here we calculate the difference between two pointers
    mov    eax, DWORD PTR _eos$[ebp]
    sub    eax, DWORD PTR _str$[ebp]
    sub    eax, 1                      ; subtract 1 and return result
    pop    ebp
    ret 0
```

*104* counting the characters in a string in the C language

(For statistics collecting purposes) if you've read this far, please click [here](http://challenges.re/56). Thanks!
We get two new instructions here: MOVSX and TEST.

The first one—MOVSX—takes a byte from an address in memory and stores the value in a 32-bit register. MOVSX stands for MOV with Sign-Extend. MOVSX sets the rest of the bits, from the 8th to the 31th, to 1 if the source byte is negative or to 0 if it is positive.

And here is why.

By default, the char type is signed in MSVC and GCC. If we have two values of which one is char and the other is int, (int is signed too), and if the first value contain -2 (coded as 0xFE) and we just copy this byte into the int container, it makes 0x000000FE, and this from the point of signed int view is 254, but not -2. In signed int, -2 is coded as 0xFFFFFFFF. So if we have to transfer 0xFE from a variable of char type to int, we have to identify its sign and extend it. That is what MOVSX does.

You can also read about it in “Signed number representations” section (2.2 on page 458).

It’s hard to say if the compiler needs to store a char variable in EDX, it could just take a 8-bit register part (for example DL). Apparently, the compiler’s register allocator works like that.

Then we see TEST EDX, EDX. You can read more about the TEST instruction in the section about bit fields (1.28 on page 307). Here this instruction just checks if the value in EDX equals to 0.

**Non-optimizing GCC**

Let’s try GCC 4.4.1:

```
  public strlen
  strlen      proc near
  eos         = dword ptr -4
  arg_0       = dword ptr  8

push ebp
mov ebp, esp
sub esp, 10h
mov eax, [ebp+arg_0]
mov [ebp+eos], eax

loc_80483F0:
  mov eax, [ebp+eos]
movzx eax, byte ptr [eax]
test al, al
setnz al
add [ebp+eos], 1
test al, al
jnz short loc_80483F0
mov edx, [ebp+eos]
mov eax, [ebp+arg_0]
mov ecx, edx
sub ecx, eax
mov eax, ecx
sub eax, 1
leave
retn

strlen   endp
```

The result is almost the same as in MSVC, but here we see MOVZX instead of MOVSX. MOVZX stands for MOV with Zero-Extend. This instruction copies a 8-bit or 16-bit value into a 32-bit register and sets the rest of the bits to 0. In fact, this instruction is convenient only because it enable us to replace this instruction pair:

```
xor eax, eax / mov al, [...].
```

On the other hand, it is obvious that the compiler could produce this code:

```
mov al, byte ptr [eax] / test al, al—it is almost the same, however, the highest bits of the EAX register will contain random noise. But let’s think it is compiler’s drawback—it cannot produce more understandable code. Strictly speaking, the compiler is not obliged to emit understandable (to humans) code at all.
```
The next new instruction for us is SETNZ. Here, if AL doesn’t contain zero, test al, al sets the ZF flag
to 0, but SETNZ, if ZF==0 (NZ stands for not zero) sets AL to 1. Speaking in natural language, if AL is not
zero, let’s jump to loc_80483F0. The compiler emits some redundant code, but let’s not forget that the
optimizations are turned off.

**Optimizing MSVC**

Now let’s compile all this in MSVC 2012, with optimizations turned on (/Ox):

```asm
Listing 1.188: Optimizing MSVC 2012 /Ob0

_str$ = 8 ; size = 4
_strlen PROC
    mov edx, DWORD PTR _str$[esp-4] ; EDX -> pointer to the string
    mov eax, edx ; move to EAX
$LL2@strlen:
    mov cl, BYTE PTR [eax] ; CL = *EAX
    inc eax ; EAX++
    test cl, cl ; CL==0?
    jne SHORT $LL2@strlen ; no, continue loop
    sub eax, edx ; calculate pointers difference
    dec eax ; decrement EAX
    ret 0
_strlen ENDP
```

Now it is all simpler. Needless to say, the compiler could use registers with such efficiency only in small
functions with a few local variables.

INC/DEC—are increment/decrement instructions, in other words: add or subtract 1 to/from a variable.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We can try this (optimized) example in OllyDbg. Here is the first iteration:

![Image of OllyDbg interface]

Figure 1.59: OllyDbg: first iteration start

We see that OllyDbg found a loop and, for convenience, wrapped its instructions in brackets. By clicking the right button on EAX, we can choose “Follow in Dump” and the memory window scrolls to the right place. Here we can see the string “hello!” in memory. There is at least one zero byte after it and then random garbage.

If OllyDbg sees a register with a valid address in it, that points to some string, it is shown as a string.

(For statistics collecting purposes) if you’ve read this far, please click [here]. Thanks!
Let's press F8 (step over) a few times, to get to the start of the body of the loop:

Figure 1.60: OllyDbg: second iteration start

We see that EAX contains the address of the second character in the string.
We have to press F8 enough number of times in order to escape from the loop:

> Figure 1.61: OllyDbg: pointers difference to be calculated now

We see that EAX now contains the address of zero byte that’s right after the string plus 1 (because INC EAX was executed regardless of whether we exit from the loop or not). Meanwhile, EDX hasn’t changed, so it still pointing to the start of the string.

The difference between these two addresses is being calculated now.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The SUB instruction just got executed:

![CPU - main thread, module ex1](image)

The difference of pointers is in the EAX register now—7. Indeed, the length of the “hello!” string is 6, but with the zero byte included—7. But `strlen()` must return the number of non-zero characters in the string. So the decrement executes and then the function returns.

**Optimizing GCC**

Let’s check GCC 4.4.1 with optimizations turned on (`-O3` key):

```c
public strlen
proc near
arg_0 = dword ptr 8

push ebp
mov ebp, esp
mov ecx, [ebp+arg_0]
mov eax, ecx

loc_8048418:

movzx edx, byte ptr [eax]
add edx, 1
test dl, dl
jnz short loc_8048418
not ecx
add eax, ecx
pop ebp
retn

strlen endp
```

Here GCC is almost the same as MSVC, except for the presence of `MOVZX`. However, here `MOVZX` could be replaced with `mov dl, byte ptr [eax].`

Figure 1.62: OllyDbg: EAX to be decremented now

The difference of pointers is in the EAX register now—7. Indeed, the length of the “hello!” string is 6, but with the zero byte included—7. But `strlen()` must return the number of non-zero characters in the string. So the decrement executes and then the function returns.
Perhaps it is simpler for GCC’s code generator to remember the whole 32-bit EDX register is allocated for a char variable and it then can be sure that the highest bits has no any noise at any point.

After that we also see a new instruction—NOT. This instruction inverts all bits in the operand. You can say that it is a synonym to the XOR ECX, 0xffffffff instruction. NOT and the following ADD calculate the pointer difference and subtract 1, just in a different way. At the start ECX, where the pointer to str is stored, gets inverted and 1 is subtracted from it.

See also: “Signed number representations” (2.2 on page 458).

In other words, at the end of the function just after loop body, these operations are executed:

```
ecx=str;
eax=eos;
ecx=(-ecx)-1;
eax+=ecx
return eax
```

... and this is effectively equivalent to:

```
ecx=str;
eax=eos;
eax-=ecx;
eax-1;
return eax
```

Why did GCC decide it would be better? Hard to guess. But perhaps the both variants are equivalent in efficiency.

**ARM**

**32-bit ARM**

**Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)**

Listing 1.189: Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```
_strlen

eos = -8
str = 4

SUB SP, SP, #8 ; allocate 8 bytes for local variables
STR R0, [SP,#8+str]
LDR R0, [SP,#8+str]
STR R0, [SP,#8+eos]
loc_2CB8 ; CODE XREF: _strlen+28
LDR R0, [SP,#8+eos]
ADD R1, R0, #1
STR R0, [SP,#8+eos]
LDRSB R0, [R0]
CMP R0, #0
BEQ loc_2CD4
B loc_2CB8
loc_2CD4 ; CODE XREF: _strlen+24
LDR R0, [SP,#8+eos]
LDR R1, [SP,#8+str]
SUB R0, R0, R1 ; R0=eos-str
SUB R0, R0, #1 ; R0=R0-1
ADD SP, SP, #8 ; free allocated 8 bytes
BX LR
```

Non-optimizing LLVM generates too much code, however, here we can see how the function works with local variables in the stack. There are only two local variables in our function: eos and str. In this listing, generated by IDA, we have manually renamed var_8 and var_4 to eos and str.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The first instructions just saves the input values into both str and eos. The body of the loop starts at label loc_2CB8.

The first three instruction in the loop body (LDR, ADD, STR) load the value of eos into R0. Then the value is incremented and saved back into eos, which is located in the stack.

The next instruction, LDRSB R0, [R0] (“Load Register Signed Byte”), loads a byte from memory at the address stored in R0 and sign-extends it to 32-bit. This is similar to the MOVVSX instruction in x86.

The compiler treats this byte as signed since the char type is signed according to the C standard. It was already written about it (1.23.1 on page 204) in this section, in relation to x86.

It has to be noted that it is impossible to use 8- or 16-bit part of a 32-bit register in ARM separately of the whole register, as it is in x86.

Apparently, it is because x86 has a huge history of backwards compatibility with its ancestors up to the 16-bit 8086 and even 8-bit 8080, but ARM was developed from scratch as a 32-bit RISC-processor.

Consequently, in order to process separate bytes in ARM, one has to use 32-bit registers anyway.

So, LDRSB loads bytes from the string into R0, one by one. The following CMP and BNE instructions check if the loaded byte is 0. If it’s not 0, control passes to the start of the body of the loop. And if it’s 0, the loop ends.

At the end of the function, the difference between eos and str is calculated, 1 is subtracted from it, and resulting value is returned via R0.

N.B. Registers were not saved in this function.

That’s because in the ARM calling convention registers R0-R3 are “scratch registers”, intended for arguments passing, and we’re not required to restore their value when the function exits, since the calling function will not use them anymore. Consequently, they may be used for anything we want.

No other registers are used here, so that is why we have nothing to save on the stack.

Thus, control may be returned back to calling function by a simple jump (BX), to the address in the LR register.

### Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

Listing 1.190: Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```
_strlen
    MOV     R1, R0

loc_2DF6
    LDRB.W R2, [R1],#1
    CMP     R2, #0
    BNE     loc_2DF6
    MVNS    R0, R0
    ADD     R0, R1
    BX      LR
```

As optimizing LLVM concludes, eos and str do not need space on the stack, and can always be stored in registers.

Before the start of the loop body, str is always in R0, and eos—in R1.

The LDRB.W R2, [R1],#1 instruction loads a byte from the memory at the address stored in R1, to R2, sign-extending it to a 32-bit value, but not just that. #1 at the instruction’s end implies “Post-indexed addressing”, which means that 1 is to be added to R1 after the byte is loaded. Read more about it: 1.39.2 on page 444.

Then you can see CMP and BNE in the body of the loop, these instructions continue looping until 0 is found in the string.

---

105 The Keil compiler treats the char type as signed, just like MSVC and GCC.
106 (PowerPC, ARM) Branch if Not Equal
MVNS\textsuperscript{107} (inverts all bits, like NOT in x86) and ADD instructions compute \( \cos - str - 1 \). In fact, these two instructions compute \( R0 = str + \cos \), which is effectively equivalent to what was in the source code, and why it is so, was already explained here (1.23.1 on page 210).

Apparently, LLVM, just like GCC, concludes that this code can be shorter (or faster).

**Optimizing Keil 6/2013 (ARM mode)**

Listing 1.191: Optimizing Keil 6/2013 (ARM mode)

<table>
<thead>
<tr>
<th>Address</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_strlen</td>
<td>MOV R1, R0</td>
<td></td>
</tr>
<tr>
<td>loc_2C8</td>
<td>LDRB R2, [R1],#1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CMP R2, #0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SUBEQ R0, R1, R0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SUBEQ R0, R0, #1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>BNE loc_2C8</td>
<td></td>
</tr>
<tr>
<td></td>
<td>BX LR</td>
<td></td>
</tr>
</tbody>
</table>

Almost the same as what we saw before, with the exception that the \( str - \cos - 1 \) expression can be computed not at the function’s end, but right in the body of the loop. The -EQ suffix, as we may recall, implies that the instruction executes only if the operands in the CMP that has been executed before were equal to each other. Thus, if R0 contains 0, both SUBEQ instructions executes and result is left in the R0 register.

**ARM64**

**Optimizing GCC (Linaro) 4.9**

```
.my_strlen:
    mov x1, x0  ; X1 is now temporary pointer (eos), acting like cursor
.L58:
    ldrb w2, [x1],1  ; load byte from X1 to W2, increment X1 (post-index)
    cbnz w2, .L58  ; Compare and Branch if NonZero: compare W2 with 0, jump to .L58 if it is not
    sub x0, x1, x0  ; calculate difference between initial pointer in X0 and current address in X1
    sub w0, w0, #1  ; decrement lowest 32-bit of result
    ret
```

The algorithm is the same as in 1.23.1 on page 205: find a zero byte, calculate the difference between the pointers and decrement the result by 1. Some comments were added by the author of this book.

The only thing worth noting is that our example is somewhat wrong: my_strlen() returns 32-bit int, while it has to return size_t or another 64-bit type.

The reason is that, theoretically, strlen() can be called for a huge blocks in memory that exceeds 4GB, so it must able to return a 64-bit value on 64-bit platforms.

Because of my mistake, the last SUB instruction operates on a 32-bit part of register, while the penultimate SUB instruction works on full the 64-bit register (it calculates the difference between the pointers).

It’s my mistake, it is better to leave it as is, as an example of how the code could look like in such case.

\textsuperscript{107}MoVe Not
my_strlen:
; function prologue
    sub     sp, sp, #32
; first argument (str) will be stored in [sp,8]
    str     x0, [sp,8]
    ldr     x0, [sp,8]
; copy "str" to "eos" variable
    str     x0, [sp,24]
    nop
.L62:
; eos++
    ldr     x0, [sp,24] ; load "eos" to X0
    add     x1, x0, 1  ; increment X0
    str     x1, [sp,24] ; save X0 to "eos"
    ; load byte from memory at address in X0 to W0
    ldrb    w0, [x0]
    ; is it zero? (WZR is the 32-bit register always contain zero)
    cmp     w0, wzr
    ; jump if not zero (Branch Not Equal)
    bne     .L62
; zero byte found. now calculate difference.
; load "eos" to X1
    ldr     x1, [sp,24]
; load "str" to X0
    ldr     x0, [sp,8]
; calculate difference
    sub     x0, x1, x0
; decrement result
    sub     w0, w0, #1
; function epilogue
    add     sp, sp, 32
    ret

It’s more verbose. The variables are often tossed here to and from memory (local stack). The same mistake here: the decrement operation happens on a 32-bit register part.

MIPS

Listing 1.192: Optimizing GCC 4.4.5 (IDA)

my_strlen:
; "eos" variable will always reside in $v1:
    move    $v1, $a0
loc_4:
; load byte at address in "eos" into $a1:
    lb      $a1, 0($v1)
    or      $at, $zero ; load delay slot, NOP
; if loaded byte is not zero, jump to loc_4:
    bnez    $a1, loc_4
; increment "eos" anyway:
    addiu   $v1, 1 ; branch delay slot
; loop finished. invert "str" variable:
    nor     $v0, $zero, $a0
; $v0=-str-1
    jr      $ra
; return value =$v1 + $v0 = eos + ( -str-1 ) = eos - str - 1
    addu    $v0, $v1, $v0 ; branch delay slot

MIPS lacks a NOT instruction, but has NOR which is OR + NOT operation.

This operation is widely used in digital electronics\(^\text{108}\). For example, the Apollo Guidance Computer used in the Apollo program, was built by only using 5600 NOR gates: [Jens Eickhoff, *Onboard Computers*,

\(^{108}\)NOR is called “universal gate”

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!

So, the NOT operation is implemented here as NOR DST, $ZERO$, SRC.

From fundamentals 2.2 on page 458 we know that bitwise inverting a signed number is the same as changing its sign and subtracting 1 from the result.

So what NOT does here is to take the value of \( str \) and transform it into \( -str - 1 \). The addition operation that follows prepares result.

### 1.23.2 Boundaries of strings

It’s interesting to note, how parameters are passed into win32 GetOpenFileName() function. In order to call it, one must set list of allowed file extensions:

```c
OPENFILENAME *LPOPENFILENAME;
...
char * filter = "Text files (*.txt)\0*.txt\0MS Word files (*.doc)\0*.doc\0\0";
...
LPOPENFILENAME = (OPENFILENAME *)malloc(sizeof(OPENFILENAME));
...
LPOPENFILENAME->lpstrFilter = filter;
...
if(GetOpenFileName(LPOPENFILENAME))
{
    ...
```

What happens here is that list of strings are passed into GetOpenFileName(). It is not a problem to parse it: whenever you encounter single zero byte, this is an item. Whenever you encounter two zero bytes, this is end of the list. If you will pass this string into printf(), it will treat first item as a single string.

So this is string, or...? It’s better say this is buffer containing several zero-terminated C-strings, which can be stored and processed as a whole.

Another example is strtok() function. It takes a string and write zero bytes in the middle of it. It thus transforms input string into some kind of buffer, which has several zero-terminated C-strings.

### 1.24 Replacing arithmetic instructions to other ones

In the pursuit of optimization, one instruction may be replaced by another, or even with a group of instructions. For example, ADD and SUB can replace each other: line 18 in listing.3.120.

For example, the LEA instruction is often used for simple arithmetic calculations: .1.6 on page 1001.

#### 1.24.1 Multiplication

**Multiplication using addition**

Here is a simple example:

```c
unsigned int f(unsigned int a)
{
    return a*8;
}
```

Multiplication by 8 is replaced by 3 addition instructions, which do the same. Apparently, MSVC's optimizer decided that this code can be faster.

Listing 1.193: Optimizing MSVC 2010

<p>| a$ = 8 | PROC |</p>
<table>
<thead>
<tr>
<th>TEXT</th>
<th>SEGMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>_f</td>
<td>; size = 4</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Multiplication using shifting

Multiplication and division instructions by a numbers that’s a power of 2 are often replaced by shift instructions.

```c
unsigned int f(unsigned int a)
{
    return a*4;
}
```

Listing 1.194: Non-optimizing MSVC 2010

Multiplication by 4 is just shifting the number to the left by 2 bits and inserting 2 zero bits at the right (as the last two bits). It is just like multiplying 3 by 100 —we just have to add two zeros at the right.

That’s how the shift left instruction works:

![Shift Left Instruction Diagram](https://example.com/diagram)

The added bits at right are always zeros.

Multiplication by 4 in ARM:

```assembly
f PROC
    LSL r0, r0, #2
    BX lr
ENDP
```

Listing 1.195: Non-optimizing Keil 6/2013 (ARM mode)

Multiplication by 4 in MIPS:

```assembly
jr $ra
sll $v0, $a0, 2 ; branch delay slot
```

Listing 1.196: Optimizing GCC 4.4.5 (IDA)

SLL is “Shift Left Logical”.

Multiplication using shifting, subtracting, and adding

It’s still possible to get rid of the multiplication operation when you multiply by numbers like 7 or 17 again by using shifting. The mathematics used here is relatively easy.
#include <stdint.h>

int f1(int a)
{
    return a*7;
};

int f2(int a)
{
    return a*28;
};

int f3(int a)
{
    return a*17;
};

---

**x86**

Listing 1.197: Optimizing MSVC 2012

```assembly
; a*7
_a$ = 8
_f1   PROC
    mov ecx, DWORD PTR _a$[esp-4]
    ; ECX=a
    lea eax, DWORD PTR [ecx*8]
    ; EAX=ECX*8
    sub eax, ecx
    ; EAX=EAX-ECX=ECX*8-ECX=ECX*7=a*7
    ret 0
_f1   ENDP

; a*28
_a$ = 8
_f2   PROC
    mov ecx, DWORD PTR _a$[esp-4]
    ; ECX=a
    lea eax, DWORD PTR [ecx*8]
    ; EAX=ECX*8
    sub eax, ecx
    ; EAX=EAX-ECX=ECX*8-ECX=ECX*7=a*7
    shl eax, 2
    ; EAX=EAX<<2=(a*7)*4=a*28
    ret 0
_f2   ENDP

; a*17
_a$ = 8
_f3   PROC
    mov eax, DWORD PTR _a$[esp-4]
    ; EAX=a
    shl eax, 4
    ; EAX=EAX<<4=EAX*16=a*16
    add eax, DWORD PTR _a$[esp-4]
    ; EAX=EAX+a=a*16+a=a*17
    ret 0
_f3   ENDP
```

**ARM**

Keil for ARM mode takes advantage of the second operand’s shift modifiers:
Listing 1.198: Optimizing Keil 6/2013 (ARM mode)

```assembly
; a*7
||f1|| PROC
RSB r0, r0, r0, LSL #3
; R0=R0<<3-R0=R0*8-R0=a*8-a=a*7
BX lr
ENDP

; a*28
||f2|| PROC
RSB r0, r0, r0, LSL #3
; R0=R0<<3-R0=R0*8-R0=a*8-a=a*7
LSL r0, r0, #2
; R0=R0<<2=R0*4=a*7*4=a*28
BX lr
ENDP

; a*17
||f3|| PROC
ADD r0, r0, r0, LSL #4
; R0=R0+R0<<4=R0+R0*16=R0*17=a*17
BX lr
ENDP
```

But there are no such modifiers in Thumb mode. It also can’t optimize f2():

Listing 1.199: Optimizing Keil 6/2013 (Thumb mode)

```assembly
; a*7
||f1|| PROC
LSLS r1, r0, #3
; R1=R0<<3=a<<3=a*8
SUBS r0, r1, r0
; R0=R1-R0=a*8-a=a*7
BX lr
ENDP

; a*28
||f2|| PROC
MOVS r1, #0x1c ; 28
; R1=28
MULS r0, r1, r0
; R0=R1*R0=28*a
BX lr
ENDP

; a*17
||f3|| PROC
LSLS r1, r0, #4
; R1=R0<<4=R0*16=a*16
ADDS r0, r0, r1
; R0=R0+R1=a+a*16=a*17
BX lr
ENDP
```

**MIPS**

Listing 1.200: Optimizing GCC 4.4.5 (IDA)

```assembly
_f1:
    sll $v0, $a0, 3
 ; $v0 = $a0<<3 = $a0*8
    jr $ra
    subu $v0, $a0 ; branch delay slot
 ; $v0 = $v0-$a0 = $a0*8-$a0 = $a0*7
_f2:
    sll $v0, $a0, 5
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
\[ v_0 = a_0 \ll 5 = a_0 \times 32 \]
\[ a_0 = a_0 \ll 2 = a_0 \times 4 \]
\[ v_0 = a_0 \times 32 - a_0 \times 4 = a_0 \times 28 \]
\[ f_3: \]
\[ v_0 = a_0 \ll 4 = a_0 \times 16 \]
\[ a_0 = a_0 + a_0 = a_0 \times 17 \]

64-bit

```c
#include <stdint.h>

int64_t f1(int64_t a)
{
    return a*7;
}

int64_t f2(int64_t a)
{
    return a*28;
}

int64_t f3(int64_t a)
{
    return a*17;
}
```

x64

Listing 1.201: Optimizing MSVC 2012

```c
;a*7
f1:
    lea rax, [0+rdi*8]
    RAX=RDIX8=a*8
    sub rax, rdi
    RAX=RAX-RDI=a*8-a=a*7
    ret

;a*28
f2:
    lea rax, [0+rdi*4]
    RAX=RDIX4=a*4
    sal rdi, 5
    RDI=RDIX4=RDIX32=a*32
    sub rdi, rax
    RDI=RDI-RAX=a*32-a*4=a*28
    mov rax, rdi
    ret

;a*17
f3:
    mov rax, rdi
    sal rax, 4
    RAX=RAX<<4=a*16
    add rax, rdi
    RAX=a*16+a=a*17
    ret
```
GCC 4.9 for ARM64 is also terse, thanks to the shift modifiers:

```
Listing 1.202: Optimizing GCC (Linaro) 4.9 ARM64

; a*7
f1:
    lsl    x1, x0, 3
    sub    x0, x1, x0
    X0=X1-X0=a*8-a=a*7
    ret

; a*28
f2:
    lsl    x1, x0, 5
    sub    x0, x1, x0, lsl 2
    X0=X1-X0=a*32-a*4=a*28
    ret

; a*17
f3:
    add    x0, x0, x0, lsl 4
    X0=X0+X0=a+a*16=a*17
    ret
```

Booth’s multiplication algorithm

There was a time when computers were big and that expensive, that some of them lacked hardware support of multiplication operation in CPU, like Data General Nova. And when one need multiplication operation, it can be provided at software level, for example, using Booth’s multiplication algorithm. This is a multiplication algorithm which uses only addition operation and shifts.

What modern optimizing compilers do, isn’t the same, but the goal (multiplication) and resources (faster operations) are the same.

1.24.2 Division

Division using shifts

Example of division by 4:

```c
unsigned int f(unsigned int a)
{
    return a/4;
}
```

We get (MSVC 2010):

```
Listing 1.203: MSVC 2010

    a$ = 8 ; size = 4
    _f PROC
    mov    eax, DWORD PTR _a$[esp-4]
    shr    eax, 2
    ret    0
    _f ENDP
```

The SHR (Shift Right) instruction in this example is shifting a number by 2 bits to the right. The two freed bits at left (e.g., two most significant bits) are set to zero. The two least significant bits are dropped. In fact, these two dropped bits are the division operation remainder.

The SHR instruction works just like SHL, but in the other direction.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
It is easy to understand if you imagine the number 23 in the decimal numeral system. 23 can be easily divided by 10 just by dropping last digit (3—division remainder). 2 is left after the operation as a quotient.

So the remainder is dropped, but that’s OK, we work on integer values anyway, these are not a real numbers!

Division by 4 in ARM:

Listing 1.204: Non-optimizing Keil 6/2013 (ARM mode)

```assembly
f PROC
    LSR    r0,r0,#2
    BX     lr
ENDP
```

Division by 4 in MIPS:

Listing 1.205: Optimizing GCC 4.4.5 (IDA)

```assembly
    jr     $ra
    srl    $v0, $a0, 2 ; branch delay slot
```

The SRL instruction is “Shift Right Logical”.

1.24.3 Exercise

• [http://challenges.re/59](http://challenges.re/59)

1.25 Floating-point unit

The FPU is a device within the main CPU, specially designed to deal with floating point numbers. It was called “coprocessor” in the past and it stays somewhat aside of the main CPU.

1.25.1 IEEE 754

A number in the IEEE 754 format consists of a sign, a significand (also called fraction) and an exponent.

1.25.2 x86

It is worth looking into stack machines or learning the basics of the Forth language, before studying the FPU in x86.

It is interesting to know that in the past (before the 80486 CPU) the coprocessor was a separate chip and it was not always pre-installed on the motherboard. It was possible to buy it separately and install it.

Starting with the 80486 DX CPU, the FPU is integrated in the CPU.

The FWAIT instruction reminds us of that fact—it switches the CPU to a waiting state, so it can wait until the FPU has finished with its work.

Another rudiment is the fact that the FPU instruction opcodes start with the so called “escape”-opcodes (D8 .. DF), i.e., opcodes passed to a separate coprocessor.

109[wiki](https://www.wikipedia.org/wiki/Stack_machine)
110[wiki](https://www.wikipedia.org/wiki/Forth_(programming_language))
111For example, John Carmack used fixed-point arithmetic ([wiki](https://www.wikipedia.org/wiki/Fixed-point_arithmetic)) values in his Doom video game, stored in 32-bit GPR registers (16 bit for integral part and another 16 bit for fractional part), so Doom could work on 32-bit computers without FPU, i.e., 80386 and 80486 SX.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
The FPU has a stack capable to holding 8 80-bit registers, and each register can hold a number in the IEEE 754 format.

They are ST(0) .. ST(7). For brevity, IDA and OllyDbg show ST(0) as ST, which is represented in some textbooks and manuals as “Stack Top”.

### 1.25.3 ARM, MIPS, x86/x64 SIMD

In ARM and MIPS the FPU is not a stack, but a set of registers, which can be accessed randomly, like GPR. The same ideology is used in the SIMD extensions of x86/x64 CPUs.

### 1.25.4 C/C++

The standard C/C++ languages offer at least two floating number types, float (single-precision, 32 bits) and double (double-precision, 64 bits).

GCC also supports the *long double* type (extended precision, 80 bit), which MSVC doesn’t.

The *float* type requires the same number of bits as the *int* type in 32-bit environments, but the number representation is completely different.

### 1.25.5 Simple example

Let’s consider this simple example:

```c
#include <stdio.h>

double f (double a, double b)
{
    return a/3.14 + b*4.1;
};

int main()
{
    printf ("%f
", f(1.2, 3.4));
};
```

**x86**

**MSVC**

Compile it in MSVC 2010:

```
Listing 1.206: MSVC 2010: f()

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
FLD takes 8 bytes from stack and loads the number into the ST(0) register, automatically converting it into the internal 80-bit format (extended precision).

FDIV divides the value in ST(0) by the number stored at address __real@40091eb851eb851f —the value 3.14 is encoded there. The assembly syntax doesn’t support floating point numbers, so what we see here is the hexadecimal representation of 3.14 in 64-bit IEEE 754 format.

After the execution of FDIV ST(0) holds the quotient.

By the way, there is also the FDIVP instruction, which divides ST(1) by ST(0), popping both these values from stack and then pushing the result. If you know the Forth language\(^\text{117}\), you can quickly understand that this is a stack machine\(^\text{118}\).

The subsequent FLD instruction pushes the value of \(b\) into the stack.

After that, the quotient is placed in ST(1), and ST(0) has the value of \(b\).

The next FMUL instruction does multiplication: \(b\) from ST(0) is multiplied by value at __real@4010666666666666 (the number 4.1 is there) and leaves the result in the ST(0) register.

The last FADDP instruction adds the two values at top of stack, storing the result in ST(1) and then popping the value of ST(0), thereby leaving the result at the top of the stack, in ST(0).

The function must return its result in the ST(0) register, so there are no any other instructions except the function epilogue after FADDP.

\(^{117}\)wikipedia.org/wiki/Forth_(programming_language)
\(^{118}\)wikipedia.org/wiki/Stack_machine

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2 pairs of 32-bit words are marked by red in the stack. Each pair is a double-number in IEEE 754 format and is passed from main().

We see how the first FLD loads a value (1.2) from the stack and puts it into ST(0):

Because of unavoidable conversion errors from 64-bit IEEE 754 floating point to 80-bit (used internally in the FPU), here we see 1.1999…, which is close to 1.2.

EIP now points to the next instruction (FDIV), which loads a double-number (a constant) from memory. For convenience, OllyDbg shows its value: 3.14

Figure 1.63: OllyDbg: the first FLD has been executed

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's trace further. FDIV has been executed, now ST(0) contains 0.382…(quotient):

Figure 1.64: OllyDbg: FDIV has been executed
Third step: the next FLD has been executed, loading 3.4 into ST(0) (here we see the approximate value 3.39999...):

At the same time, quotient is pushed into ST(1). Right now, EIP points to the next instruction: FMUL. It loads the constant 4.1 from memory, which OllyDbg shows.

Figure 1.65: OllyDbg: the second FLD has been executed

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Figure 1.66: OllyDbg: the FMUL has been executed
Next: the FADDP has been executed, now the result of the addition is in ST(0), and ST(1) is cleared:

The result is left in ST(0), because the function returns its value in ST(0).

main() takes this value from the register later.

We also see something unusual: the 13.93...value is now located in ST(7). Why?

As we have read some time before in this book, the FPU registers are a stack: 1.25.2 on page 220. But this is a simplification.

Imagine if it was implemented in hardware as it's described, then all 7 register's contents must be moved (or copied) to adjacent registers during pushing and popping, and that's a lot of work.

In reality, the FPU has just 8 registers and a pointer (called TOP) which contains a register number, which is the current “top of stack”.

When a value is pushed to the stack, TOP is pointed to the next available register, and then a value is written to that register.

The procedure is reversed if a value is popped, however, the register which has been freed is not cleared (it could possibly be cleared, but this is more work which can degrade performance). So that's what we see here.

It can be said that FADDP saved the sum in the stack, and then popped one element.

But in fact, this instruction saved the sum and then shifted TOP.

More precisely, the registers of the FPU are a circular buffer.

GCC

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
GCC 4.4.1 (with -O3 option) emits the same code, just slightly different:

```
Listing 1.207: Optimizing GCC 4.4.1

public f
    proc near
    arg_0 = qword ptr 8
    arg_8 = qword ptr 10h
    push ebp
    fld ds:dbl_8048608 ; 3.14
    ; stack state now: ST(0) = 3.14
    mov ebp, esp
    fld [ebp+arg_0]
    ; stack state now: ST(0) = result of division
    fdiv [ebp+arg_8]
    ; stack state now: ST(0) = result of multiplication, ST(1) = result of division
    pop ebp
    faddp st(1), st
    ; stack state now: ST(0) = result of addition
    retn
f
    endp
```

The difference is that, first of all, 3.14 is pushed to the stack (into ST(0)), and then the value in arg_0 is divided by the value in ST(0).

FDIVR stands for *Reverse Divide* — to divide with divisor and dividend swapped with each other. There is no likewise instruction for multiplication since it is a commutative operation, so we just have FMUL without its -R counterpart.

FADDP adds the two values but also pops one value from the stack. After that operation, ST(0) holds the sum.

**ARM: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)**

Until ARM got standardized floating point support, several processor manufacturers added their own instructions extensions. Then, VFP (*Vector Floating Point*) was standardized.

One important difference from x86 is that in ARM, there is no stack, you work just with registers.

```
Listing 1.208: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
So, we see here new some registers used, with D prefix.

These are 64-bit registers, there are 32 of them, and they can be used both for floating-point numbers (double) but also for SIMD (it is called NEON here in ARM).

There are also 32 32-bit S-registers, intended to be used for single precision floating pointer numbers (float).

It is easy to memorize: D-registers are for double precision numbers, while S-registers—for single precision numbers. More about it: .2.3 on page 1013.

Both constants (3.14 and 4.1) are stored in memory in IEEE 754 format.

VLDR and VMOV, as it can be easily deduced, are analogous to the LDR and MOV instructions, but they work with D-registers.

It has to be noted that these instructions, just like the D-registers, are intended not only for floating point numbers, but can be also used for SIMD (NEON) operations and this will also be shown soon.

The arguments are passed to the function in a common way, via the R-registers, however each number that has double precision has a size of 64 bits, so two R-registers are needed to pass each one.

VMOV D17, R0, R1 at the start, composes two 32-bit values from R0 and R1 into one 64-bit value and saves it to D17.

VMOV R0, R1, D16 is the inverse operation: what has been in D16 is split in two registers, R0 and R1, because a double-precision number that needs 64 bits for storage, is returned in R0 and R1.

VDIV, VMUL and VADD, are instruction for processing floating point numbers that compute quotient, product and sum, respectively.

The code for Thumb-2 is same.

```

Keil generated code for a processor without FPU or NEON support.

The double-precision floating-point numbers are passed via generic R-registers, and instead of FPU-instructions, service library functions are called (like __aeabi_dmul, __aeabi_ddiv, __aeabi_dadd) which emulate multiplication, division and addition for floating-point numbers.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Of course, that is slower than FPU-coprocessor, but it's still better than nothing.

By the way, similar FPU-emulating libraries were very popular in the x86 world when coprocessors were rare and expensive, and were installed only on expensive computers.

The FPU-coprocessor emulation is called soft float or armel (emulation) in the ARM world, while using the coprocessor's FPU-instructions is called hard float or armhf.

**ARM64: Optimizing GCC (Linaro) 4.9**

Very compact code:

```
Listing 1.209: Optimizing GCC (Linaro) 4.9

f:
; D0 = a, D1 = b

    fmov   x0, d0
; X0 = D0 = b*4.1
    fmov   d0, x1
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Non-optimizing GCC is more verbose.

There is a lot of unnecessary value shuffling, including some clearly redundant code (the last two FM0V instructions). Probably, GCC 4.9 is not yet good in generating ARM64 code.

What is worth noting is that ARM64 has 64-bit registers, and the D-registers are 64-bit ones as well.

So the compiler is free to save values of type \texttt{double} in GPRs instead of the local stack. This isn’t possible on 32-bit CPUs.

And again, as an exercise, you can try to optimize this function manually, without introducing new instructions like FMADD.

### 1.25.6 Passing floating point numbers via arguments

```c
#include <math.h>
#include <stdio.h>

int main ()
{
    double a = 32.01;
    double b = 1.54;
    printf (“%lf\n”, pow (a, b));
    return 0;
}
```

#### x86

Let’s see what we get in (MSVC 2010):

```
Listing 1.211: MSVC 2010

CONST SEGMENT
__real@40400147ae147ae1 DQ 040400147ae147ae1r ; 32.01
__real@3ff8a3d70a3d70a4 DQ 03ff8a3d70a3d70a4r ; 1.54
CONST ENDS

_main PROC
    push ebp
    mov ebp, esp
    sub esp, 8 ; allocate space for the first variable
    fld QWORD PTR __real@3ff8a3d70a3d70a4
    fstp QWORD PTR [esp]
    sub esp, 8 ; allocate space for the second variable
    fld QWORD PTR __real@40400147ae147ae1
    fstp QWORD PTR [esp]
    call _pow
    add esp, 8 ; return back place of one variable.
    ; in local stack here 8 bytes still reserved for us.
    ; result now in ST(0)
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
fstp QWORD PTR [esp] ; move result from ST(0) to local stack for printf()
push OFFSET $SG2651
call _printf
add esp, 12
xor eax, eax
pop ebp
ret 0

FLT and FSTP move variables between the data segment and the FPU stack. pow() takes both values from the stack and returns its result in the ST(0) register. printf() takes 8 bytes from the local stack and interprets them as double type variable.

By the way, a pair of MOV instructions could be used here for moving values from the memory into the stack, because the values in memory are stored in IEEE 754 format, and pow() also takes them in this format, so no conversion is necessary. That’s how it’s done in the next example, for ARM: 1.25.6.

ARM + Non-optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

main

var_C = -0xC

    PUSH {R7,LR}
    MOV R7, SP
    SUB SP, SP, #4
    VLDR D16, =32.01
    VMOV R0, R1, D16
    VLDR D16, =1.54
    VMOV R2, R3, D16
    BLX _pow
    VMOV D16, R0, R1
    MOV R0, 0xfc1 ; "32.01 ^ 1.54 = %lf\n"
    ADD R0, PC
    VMOV R1, R2, D16
    BLX _printf
    MOV R1, 0
    STR R0, [SP,#0xC+var_C]
    MOV R0, R1
    ADD SP, SP, #4
    POP {R7,PC}

dbl_2F90 DCFD 32.01 ; DATA XREF: _main+6
dbl_2F98 DCFD 1.54 ; DATA XREF: _main+E

As it was mentioned before, 64-bit floating pointer numbers are passed in R-registers pairs.

This code is a bit redundant (certainly because optimization is turned off), since it is possible to load values into the R-registers directly without touching the D-registers.

So, as we see, the _pow function receives its first argument in R0 and R1, and its second one in R2 and R3. The function leaves its result in R0 and R1. The result of _pow is moved into D16, then in the R1 and R2 pair, from where printf() takes the resulting number.

ARM + Non-optimizing Keil 6/2013 (ARM mode)

main

    STMFD SP!, {R4-R6,LR}
    LDR R2, =0xA3D70A4 ; y
    LDR R3, =0x3FF8A3D7
    LDR R0, =0xAE147AE1 ; x
    LDR R1, =0x40400147
    BL pow

119 a standard C function, raises a number to the given power (exponentiation)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
D-registers are not used here, just R-register pairs.

**ARM64 + Optimizing GCC (Linaro) 4.9**

Listing 1.212: Optimizing GCC (Linaro) 4.9

```assembly
f:
    stp x29, x30, [sp, -16]!
    add x29, sp, 0
    ldr d1, .LC1 ; load 1.54 into D1
    ldr d0, .LC0 ; load 32.01 into D0
    bl pow ; result of pow() in D0
    adrp x0, .LC2
    add x0, x0, :lo12:.LC2
    bl printf
    mov w0, 0
    ldp x29, x30, [sp], 16
    ret

.LC0:
    ; 32.01 in IEEE 754 format
    .word -1374389535
    .word 1077936455

.LC1:
    ; 1.54 in IEEE 754 format
    .word 171798692
    .word 1073259479

.LC2:
    .string "32.01 ^ 1.54 = %lf\n"
```

The constants are loaded into D0 and D1: pow() takes them from there. The result will be in D0 after the execution of pow(). It is to be passed to printf() without any modification and moving, because printf() takes arguments of integral types and pointers from X-registers, and floating point arguments from D-registers.

### 1.25.7 Comparison example

Let's try this:

```c
#include <stdio.h>

double d_max (double a, double b) {
    if (a>b)
        return a;
    return b;
};

int main() {

```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
printf ("%f\n", d_max (1.2, 3.4));
printf ("%f\n", d_max (5.6, -4));
}

Despite the simplicity of the function, it will be harder to understand how it works.

x86

Non-optimizing MSVC

MSVC 2010 generates the following:

```
PUBLIC _d_max
_TEXT SEGMENT
_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_d_max PROC
    push ebp
    mov ebp, esp
    fld QWORD PTR _b$[ebp]
    ; current stack state: ST(0) = b
    ; compare _b (ST(0)) and _a, and pop register
    fcomp QWORD PTR _a$[ebp]
    ; stack is empty here
    fnstsw ax
    test ah, 5
    jp SHORT $LN1@d_max
    ; we are here only if a>b
    fld QWORD PTR _a$[ebp]
    jmp SHORT $LN2@d_max
$LN1@d_max:
    fld QWORD PTR _b$[ebp]
$LN2@d_max:
    pop ebp
    ret 0
_d_max ENDP
```

So, FLD loads _b into ST(0).

FCOMP compares the value in ST(0) with what is in _a and sets C3/C2/C0 bits in FPU status word register, accordingly. This is a 16-bit register that reflects the current state of the FPU.

After the bits are set, the FCOMP instruction also pops one variable from the stack. This is what distinguishes it from FCOM, which is just compares values, leaving the stack in the same state.

Unfortunately, CPUs before Intel P6\(^\text{120}\) don’t have any conditional jumps instructions which check the C3/C2/C0 bits. Perhaps, it is a matter of history (recall: FPU was a separate chip in past).

Modern CPU starting at Intel P6 have FCOMI/FCOMIP/FUCOMI/FUCOMIP instructions —which do the same, but modify the ZF/PF/CF CPU flags.

The FNSTSW instruction copies FPU the status word register to AX. C3/C2/C0 bits are placed at positions 14/10/8, they are at the same positions in the AX register and all they are placed in the high part of AX —AH.

- If \(b > a\) in our example, then C3/C2/C0 bits are to be set as following: 0, 0, 0.
- If \(a > b\), then the bits are: 0, 0, 1.
- If \(a = b\), then the bits are: 1, 0, 0.

\(^{120}\)Intel P6 is Pentium Pro, Pentium II, etc.
If the result is unordered (in case of error), then the set bits are: 1, 1, 1.

This is how C3/C2/C0 bits are located in the AX register:

```
  14  10  8
 C3 C2 C1 C0
```

This is how C3/C2/C0 bits are located in the AH register:

```
  6  2  1  0
 C3 C2 C1 C0
```

After the execution of `test ah, 5`\(^{121}\), only C0 and C2 bits (on 0 and 2 position) are considered, all other bits are just ignored.

Now let's talk about the parity flag, another notable historical rudiment.

This flag is set to 1 if the number of ones in the result of the last calculation is even, and to 0 if it is odd.

Let's look into Wikipedia\(^ {122}\):

One common reason to test the parity flag actually has nothing to do with parity. The FPU has four condition flags (C0 to C3), but they cannot be tested directly, and must instead be first copied to the flags register. When this happens, C0 is placed in the carry flag, C2 in the parity flag and C3 in the zero flag. The C2 flag is set when e.g. incomparable floating point values (NaN or unsupported format) are compared with the FUCOM instructions.

As noted in Wikipedia, the parity flag used sometimes in FPU code, let’s see how.

The PF flag is to be set to 1 if both C0 and C2 are set to 0 or both are 1, in which case the subsequent JP (jump if PF==1) is triggering. If we recall the values of C3/C2/C0 for various cases, we can see that the conditional jump JP is triggering in two cases: if \( b > a \) or \( a = b \) (C3 bit is not considered here, since it has been cleared by the `test ah, 5` instruction).

It is all simple after that. If the conditional jump has been triggered, FLD loads the value of \(_b\) in ST(0), and if it hasn’t been triggered, the value of \(_a\) is loaded there.

**And what about checking C2?**

The C2 flag is set in case of error (\(\text{NaN}\), etc.), but our code doesn’t check it.

If the programmer cares about FPU errors, he/she must add additional checks.

\(^{121}\)5=101b
\(^{122}\)wikipedia.org/wiki/Parity_flag

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's load the example into OllyDbg:

Figure 1.68: OllyDbg: first FLD has been executed

Current arguments of the function: \( a = 1.2 \) and \( b = 3.4 \) (We can see them in the stack: two pairs of 32-bit values). \( b \) (3.4) is already loaded in ST(0). Now FCOMP is being executed. OllyDbg shows the second FCOMP argument, which is in stack right now.
FCOMP has been executed:

Figure 1.69: OllyDbg: FCOMP has been executed

We see the state of the FPU's condition flags: all zeros. The popped value is reflected as ST(7), it was written earlier about reason for this: **1.25.5 on page 227**.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We see that the AX register contain zeros: indeed, all condition flags are zero. (OllyDbg disassembles the FNSTSW instruction as FSTSW—they are synonyms).
TEST has been executed:

Figure 1.71: OllyDbg: TEST has been executed

The PF flag is set to 1.

Indeed: the number of bits set in 0 is 0 and 0 is an even number. OllyDbg disassembles JP as JPE\textsuperscript{123}—they are synonyms. And it is about to trigger now.

\textsuperscript{123}Jump Parity Even (x86 instruction)

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
JPE triggered, FLD loads the value of $b (3.4) in ST(0):

The function finishes its work.

Figure 1.72: OllyDbg: the second FLD has been executed
Let's load example into OllyDbg:

Figure 1.73: OllyDbg: first FLD executed

Current function arguments: $a = 5.6$ and $b = -4$. $b$ (-4) is already loaded in ST(0). FCOMP about to execute now. OllyDbg shows the second FCOMP argument, which is in stack right now.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Figure 1.74: OllyDbg: FCOMP executed

We see the state of the FPU’s condition flags: all zeros except C0.
Figure 1.75: OllyDbg: FNSTSW executed

We see that the AX register contains 0x100: the C0 flag is at the 8th bit.
The PF flag is cleared. Indeed:
the count of bits set in 0x100 is 1 and 1 is an odd number. JPE is being skipped now.
JPE hasn’t been triggered, so FLD loads the value of $a$ (5.6) in ST(0):

![CPU - main thread, module d_max](image)

Figure 1.77: OllyDbg: second FLD executed

The function finishes its work.

Optimizing MSVC 2010

Listing 1.214: Optimizing MSVC 2010

```
a$ = 8 ; size = 8
b$ = 16 ; size = 8

_d_max PROC
   fld QWORD PTR _b$[esp-4]
   fld QWORD PTR _a$[esp-4]

; current stack state: ST(0) = _a, ST(1) = _b
    fcom  ST(1) ; compare _a and ST(1) = (_b)
    fnstsw ax
    test ah, 65 ; 00000004H
    jne SHORT $LN5@d_max

; copy ST(0) to ST(1) and pop register,
; leave (_a) on top
    fstp ST(1)

; current stack state: ST(0) = _a
    ret 0

$LN5@d_max:
; copy ST(0) to ST(0) and pop register,
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
FCOM differs from FCOMP in the sense that it just compares the values and doesn’t change the FPU stack. Unlike the previous example, here the operands are in reverse order, which is why the result of the comparison in C3/C2/C0 is different:

- If \( a > b \) in our example, then C3/C2/C0 bits are to be set as: 0, 0, 0.
- If \( b > a \), then the bits are: 0, 0, 1.
- If \( a = b \), then the bits are: 1, 0, 0.

The test ah, 65 instruction leaves just two bits —C3 and C0. Both will be zero if \( a > b \); in that case the JNE jump will not be triggered. Then FSTP ST(1) follows —this instruction copies the value from ST(0) to the operand and pops one value from the FPU stack. In other words, the instruction copies ST(0) (where the value of \( _a \) is now) into ST(1). After that, two copies of \( _a \) are at the top of the stack. Then, one value is popped. After that, ST(0) contains \( _a \) and the function finishes.

The conditional jump JNE is triggering in two cases: if \( b > a \) or \( a = b \). ST(0) is copied into ST(0), it is just like an idle (NOP) operation, then one value is popped from the stack and the top of the stack (ST(0)) is contain what has been in ST(1) before (that is \( _b \)). Then the function finishes. The reason this instruction is used here probably is because the FPU has no other instruction to pop a value from the stack and discard it.

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Both FLD are executed:

**Figure 1.78**: OllyDbg: both FLD are executed

FCOM being executed: OllyDbg shows the contents of ST(0) and ST(1) for convenience.

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
Figure 1.79: OllyDbg: FCOM has been executed

C0 is set, all other condition flags are cleared.
FNSTSW has been executed, AX=0x3100:

```
Figure 1.80: OllyDbg: FNSTSW is executed
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
TEST is executed:

![OllyDbg screenshot showing the CPU registers and disassembly](Image)

Figure 1.81: OllyDbg: TEST is executed

ZF=0, conditional jump is about to trigger now.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
FSTP ST (or FSTP ST(0)) has been executed — 1.2 has been popped from the stack, and 3.4 was left on top:

![CPU main thread, module d_max](image)

Figure 1.82: OllyDbg: FSTP is executed

We see that the FSTP ST instruction works just like popping one value from the FPU stack.
Both FLD are executed:

Figure 1.83: OllyDbg: both FLD are executed

FCOM is about to execute.
Figure 1.84: OllyDbg: FCOM is finished

All conditional flags are cleared.
Figure 1.85: OllyDbg: FNSTSW has been executed

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Figure 1.86: OllyDbg: TEST has been executed

ZF=1, jump will not happen now.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
FSTP ST(1) has been executed: a value of 5.6 is now at the top of the FPU stack.

Figure 1.87: OllyDbg: FSTP has been executed

We now see that the FSTP ST(1) instruction works as follows: it leaves what has been at the top of the stack, but clears ST(1).

GCC 4.4.1

locret_8048456:
    leave
    retn

d_max endp

FUCOMPP is almost like FCOM, but pops both values from the stack and handles “not-a-numbers” differently. A bit about not-a-numbers.

The FPU is able to deal with special values which are not-a-numbers or NaNs\(^{124}\). These are infinity, result of division by 0, etc. Not-a-numbers can be “quiet” and “signaling”. It is possible to continue to work with “quiet” NaNs, but if one tries to do any operation with “signaling” NaNs, an exception is to be raised.

FCOM raising an exception if any operand is NaN. FUCOM raising an exception only if any operand is a signaling NaN (SNaN).

The next instruction is SAHF (Store AH into Flags) —this is a rare instruction in code not related to the FPU. 8 bits from AH are moved into the lower 8 bits of the CPU flags in the following order:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>4</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SF</td>
<td>ZF</td>
<td>AF</td>
<td>PF</td>
<td>CF</td>
</tr>
</tbody>
</table>

Let’s recall that FNSTSW moves the bits that interest us (C3/C2/C0) into AH and they are in positions 6, 2, 0 of the AH register:

<table>
<thead>
<tr>
<th>6</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C3</td>
<td>C2</td>
<td>C1</td>
<td>C0</td>
</tr>
</tbody>
</table>

In other words, the fnstsw ax / sahf instruction pair moves C3/C2/C0 into ZF, PF and CF.

Now let’s also recall the values of C3/C2/C0 in different conditions:

- If \(a\) is greater than \(b\) in our example, then C3/C2/C0 are to be set to: 0, 0, 0.
- If \(a\) is less than \(b\), then the bits are to be set to: 0, 0, 1.
- If \(a = b\), then: 1, 0, 0.

In other words, these states of the CPU flags are possible after three FUCOMPP/FNSTSW/SAHF instructions:

- If \(a > b\), the CPU flags are to be set as: ZF=0, PF=0, CF=0.
- If \(a < b\), then the flags are to be set as: ZF=0, PF=0, CF=1.

\(^{124}\)wikipedia.org/wiki/NaN

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
• And if \( a = b \), then: ZF=1, PF=0, CF=0.

Depending on the CPU flags and conditions, SETNBE stores 1 or 0 to AL. It is almost the counterpart of JNBE, with the exception that SETcc\textsuperscript{125} stores 1 or 0 in AL, but Jcc does actually jump or not. SETNBE stores 1 only if CF=0 and ZF=0. If it is not true, 0 is to be stored into AL.

Only in one case both CF and ZF are 0: if \( a > b \).

Then 1 is to be stored to AL, the subsequent JZ is not to be triggered and the function will return \_a. In all other cases, \_b is to be returned.

**Optimizing GCC 4.4.1**

Listing 1.216: Optimizing GCC 4.4.1

```plaintext
public d_max

d_max proc near

arg_0 = qword ptr 8
arg_8 = qword ptr 10h

push ebp
mov ebp, esp
fld [ebp+arg_0] ; _a
fld [ebp+arg_8] ; _b

; stack state now: ST(0) = _b, ST(1) = _a
fxch st(1)

; stack state now: ST(0) = _a, ST(1) = _b
fucom st(1) ; compare _a and _b
fnstsw ax
sahf
ja short loc_8048448

; store ST(0) to ST(0) (idle operation),
; pop value at top of stack,
; leave _b at top
fstp st
jmp short loc_804844A

loc_8048448:
; store _a to ST(1), pop value at top of stack, leave _a at top
fstp st(1)

loc_804844A:
pop ebp
ret

_d_max endp
```

It is almost the same except that s used after SAHF. Actually, conditional jump instructions that check “larger”, “lesser” or “equal” for unsigned number comparison (these are JA, JAE, JB, JBE, JE/JZ, JNA, JNAE, JNB, JNBE, JNE/JNZ) check only flags CF and ZF.

Let’s recall where bits C3/C2/C0 are located in the AH register after the execution of FSTSW/FNSTSW:

```
6  5  4  3  2  1  0
| C3 | C2 | C1 | C0 |
```

Let’s also recall, how the bits from AH are stored into the CPU flags after the execution of SAHF:

```
7  6  5  4  3  2  1  0
| SF | ZF | AF | PF | CF |
```

After the comparison, the C3 and C0 bits are moved into ZF and CF, so the conditional jumps are able work after. s triggering if both CF are ZF zero.

\textsuperscript{125}cc is condition code

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The conditional jumps instructions listed here can be used after a FNSTSW/SAHF instruction pair. Apparently, the FPU C3/C2/C0 status bits were placed there intentionally, to easily map them to base CPU flags without additional permutations?

**GCC 4.8.1 with -O3 optimization turned on**

Some new FPU instructions were added in the P6 Intel family\(^{126}\). These are FUCOMI (compare operands and set flags of the main CPU) and FCMOVcc (works like CMOVcc, but on FPU registers).

Apparently, the maintainers of GCC decided to drop support of pre-P6 Intel CPUs (early Pentiums, 80486, etc.).

And also, the FPU is no longer separate unit in P6 Intel family, so now it is possible to modify/check flags of the main CPU from the FPU.

So what we get is:

### Listing 1.217: Optimizing GCC 4.8.1

```plaintext
fld QWORD PTR [esp+4] ; load "a"
fld QWORD PTR [esp+12] ; load "b"
fch st(1)
; ST0=a, ST1=b
; compare "a" and "b"
fcomi st, st(1)
; copy ST1 ("b" here) to ST0 if a<=b
; leave "a" in ST0 otherwise
fcomovbe st, st(1)
; discard value in ST1
fstp st(1)
ret
```

Hard to guess why FXCH (swap operands) is here.

It’s possible to get rid of it easily by swapping the first two FLD instructions or by replacing FCMOVBE (below or equal) by FMOVBE (above). Probably it’s a compiler inaccuracy.

So FUCOMI compares ST(0) (a) and ST(1) (b) and then sets some flags in the main CPU. FCMOVBE checks the flags and copies ST(1) (b here at the moment) to ST(0) (a here) if ST0(a) <= ST1(b). Otherwise (a > b), it leaves a in ST(0).

The last FSTP leaves ST(0) on top of the stack, discarding the contents of ST(1).

Let’s trace this function in GDB:

Using "ni", let's execute the first two FLD instructions.

Let's examine the FPU registers (line 33).

As it was mentioned before, the FPU registers set is a circular buffer rather than a stack (1.25.5 on page 227). And GDB doesn’t show STx registers, but internal the FPU registers (Rx). The arrow (at line 35) points to the current top of the stack.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
You can also see the T0P register contents in Status Word (line 44)—it is 6 now, so the stack top is now pointing to internal register 6.

The values of $a$ and $b$ are swapped after FXCH is executed (line 54). FUCOMI is executed (line 83). Let’s see the flags: CF is set (line 95). FCMOVBE has copied the value of $b$ (see line 104).

FSTP leaves one value at the top of stack (line 136). The value of T0P is now 7, so the FPU stack top is pointing to internal register 7.

**ARM**

**Optimizing Xcode 4.6.3 (LLVM) (ARM mode)**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>D16, R2, R3 ; b</th>
<th>D17, R0, R1 ; a</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMOV</td>
<td>D16, R2, R3 ; b</td>
<td>D17, R0, R1 ; a</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>VMOV</td>
<td>R0, R1, D16</td>
<td></td>
</tr>
<tr>
<td>BX</td>
<td>LR</td>
<td></td>
</tr>
</tbody>
</table>

A very simple case. The input values are placed into the D17 and D16 registers and then compared using the VCMPE instruction.

Just like in the x86 coprocessor, the ARM coprocessor has its own status and flags register (FPSCR\(^{127}\)), since there is a necessity to store coprocessor-specific flags. And just like in x86, there are no conditional jump instruction in ARM, that can check bits in the status register of the coprocessor. So there is VMRS, which copies 4 bits (N, Z, C, V) from the coprocessor status word into bits of the general status register (APSR\(^{128}\)).

VMOVGT is the analog of the MOVGT, instruction for D-registers, it executes if one operand is greater than the other while comparing (GT—Greater Than).

If it gets executed, the value of $a$ is to be written into D16 (that is currently stored in D17). Otherwise the value of $b$ stays in the D16 register.

The penultimate instruction VMOV prepares the value in the D16 register for returning it via the R0 and R1 register pair.

**Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)**

<td>LR</td>
<td></td>
</tr>
</tbody>
</table>

Almost the same as in the previous example, however slightly different. As we already know, many instructions in ARM mode can be supplemented by condition predicate. But there is no such thing in Thumb mode. There is no space in the 16-bit instructions for 4 more bits in which conditions can be encoded.

However, Thumb-2 was extended to make it possible to specify predicates to old Thumb instructions. Here, in the IDA-generated listing, we see the VMOVGT instruction, as in previous example.

\(^{127}\)(ARM) Floating-Point Status and Control Register

\(^{128}\)(ARM) Application Program Status Register
In fact, the usual VMOV is encoded there, but IDA adds the -GT suffix to it, since there is a IT GT instruction placed right before it.

The IT instruction defines a so-called \textit{if-then block}.

After the instruction it is possible to place up to 4 instructions, each of them has a predicate suffix. In our example, IT GT implies that the next instruction is to be executed, if the \textit{GT (Greater Than)} condition is true.

Here is a more complex code fragment, by the way, from Angry Birds (for iOS):

\begin{verbatim}
... ITT  NE
ITE NE
VMOVNE r2, r3, d16
VMOSEQ r2, r3, d17
BLX _objc_msgSend ; not suffixed
...

ITE stands for \textit{if-then-else} and it encodes suffixes for the next two instructions.

The first instruction executes if the condition encoded in ITE \textit{(NE, not equal)} is true at, and the second—if the condition is not true. (The inverse condition of NE is EQ \textit{(equal)}).

The instruction followed after the second VMOV (or VMOSEQ) is a normal one, not suffixed (BLX).

One more that’s slightly harder, which is also from Angry Birds:

\begin{verbatim}
... ITTTT  EQ
ITTTT  EQ
MOV EQ  r0, r4
ADDEQ  sp, sp, #0x20
POPEQ  {r8,r10}
POPEQ  {r4-r7,pc}
BLX  ___stack_chk_fail ; not suffixed
...

Four “T” symbols in the instruction mnemonic mean that the four subsequent instructions are to be executed if the condition is true.

That’s why IDA adds the -EQ suffix to each one of them.

And if there was, for example, ITEEE EQ \textit{(if-then-else-else-else)}, then the suffixes would have been set as follows:

-EQ  
-NE  
-NE  
-NE

Another fragment from Angry Birds:

\begin{verbatim}
... CMP.W r0, #0xFFFFFFFF
ITTE LE
SUBLE.W r10, r0, #1
NEGLE r0, r0
MOVGT r10, r0
MOV r6, #0 ; not suffixed
CBZ r0, loc_1E7E32 ; not suffixed
...

ITTE \textit{(if-then-then-else)} implies that the 1st and 2nd instructions are to be executed if the LE \textit{(Less or Equal)} condition is true, and the 3rd—if the inverse condition (GT—\textit{Greater Than}) is true.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Compilers usually don’t generate all possible combinations.

For example, in the mentioned Angry Birds game (classic version for iOS) only these variants of the IT instruction are used: IT, ITE, ITT, ITTE, ITTT, ITTTT. How to learn this? In IDA, it is possible to produce listing files, so it was created with an option to show 4 bytes for each opcode. Then, knowing the high part of the 16-bit opcode (IT is 0xBF), we do the following using grep:

```
cat AngryBirdsClassic.lst | grep " BF" | grep "IT" > results.lst
```

By the way, if you program in ARM assembly language manually for Thumb-2 mode, and you add conditional suffixes, the assembler will add the IT instructions automatically with the required flags where it is necessary.

**Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)**

<table>
<thead>
<tr>
<th>Listing 1.224: Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td>b = -0x20</td>

</tr>
<tr>
<td>MOVs R1, R7</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Keil doesn’t generate FPU-instructions since it cannot rely on them being supported on the target CPU, and it cannot be done by straightforward bitwise comparing. So it calls an external library function to do the comparison: \texttt{__aeabi_cdrcmple}.

N.B. The result of the comparison is to be left in the flags by this function, so the following BCS (\textit{Carry set—Greater than or equal}) instruction can work without any additional code.

**ARM64**

**Optimizing GCC (Linaro) 4.9**

```
d_max:
; D0 - a, D1 - b
    fcmpe   d0, d1
    fcseq   d0, d0, d1, gt
; now result in D0
    ret
```

The ARM64 \textbf{ISA} has FPU-instructions which set \texttt{APSR} the CPU flags instead of \texttt{FPSCR} for convenience. The \texttt{FPU} is not a separate device here anymore (at least, logically). Here we see \texttt{FCMPE}. It compares the two values passed in \texttt{D0} and \texttt{D1} (which are the first and second arguments of the function) and sets \texttt{APSR} flags (N, Z, C, V).

\texttt{FCSEL (Floating Conditional Select)} copies the value of \texttt{D0} or \texttt{D1} into \texttt{D0} depending on the condition (GT—Greater Than), and again, it uses flags in \texttt{APSR} register instead of \texttt{FPSCR}.

This is much more convenient, compared to the instruction set in older CPUs.

If the condition is true (GT), then the value of \texttt{D0} is copied into \texttt{D0} (i.e., nothing happens). If the condition is not true, the value of \texttt{D1} is copied into \texttt{D0}.

**Non-optimizing GCC (Linaro) 4.9**

```
d_max:
; save input arguments in "Register Save Area"
    sub    sp, sp, #16
    str    d0, [sp,8]
    str    d1, [sp]
; reload values
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    fmov   d0, x1
    fmov   d1, x0
; D0 - a, D1 - b
    fcmpe   d0, d1
    ble    .L76
; a>b; load D0 (a) into X0
    ldr    x0, [sp,8]
    b      .L74
.L76:
; a<=b; load D1 (b) into X0
    ldr    x0, [sp]
.L74:
; result in X0
    fmov   d0, x0
; result in D0
    add    sp, sp, 16
    ret
```

(For statistics collecting purposes) if you’ve read this far, please click \texttt{here}. Thanks!
Non-optimizing GCC is more verbose.

First, the function saves its input argument values in the local stack (Register Save Area). Then the code reloads these values into registers X0/X1 and finally copies them to D0/D1 to be compared using FCMPE. A lot of redundant code, but that is how non-optimizing compilers work. FCMPE compares the values and sets the APSR flags. At this moment, the compiler is not thinking yet about the more convenient FCSEL instruction, so it proceed using old methods: using the BLE instruction (Branch if Less than or Equal). In the first case \((a > b)\), the value of \(a\) gets loaded into X0. In the other case \((a \leq b)\), the value of \(b\) gets loaded into X0. Finally, the value from X0 gets copied into D0, because the return value needs to be in this register.

**Exercise**

As an exercise, you can try optimizing this piece of code manually by removing redundant instructions and not introducing new ones (including FCSEL).

**Optimizing GCC (Linaro) 4.9—float**

Let’s also rewrite this example to use *float* instead of *double*.

```c
float f_max (float a, float b)
{
    if (a>b)
        return a;
    return b;
}
```

```assembly
f_max:  
; S0 - a, S1 - b
 fcmpe s0, s1  
 fcxsel s0, s0, s1, gt 
 ; now result in S0 
    ret
```

It is the same code, but the S-registers are used instead of D- ones. It’s because numbers of type *float* are passed in 32-bit S-registers (which are in fact the lower parts of the 64-bit D-registers).

**MIPS**

The co-processor of the MIPS processor has a condition bit which can be set in the FPU and checked in the CPU.

Earlier MIPS-es have only one condition bit (called FCC0), later ones have 8 (called FCC7-FCC0).

This bit (or bits) are located in the register called FCCR.

```assembly
Listing 1.226: Optimizing GCC 4.4.5 (IDA)

d_max:  
; set FPU condition bit if $f14<$f12 (b<a):
 c.lt.d $f14, $f12  
 or $at, $zero ; NOP  
 ; jump to locret_14 if condition bit is set
 bclt locret_14 
 ; this instruction is always executed (set return value to "a"):
 mov.d $f0, $f12 ; branch delay slot  
 ; this instruction is executed only if branch was not taken (i.e., if b>=a)  
 ; set return value to "b":
 mov.d $f0, $f14  

locret_14:  
    jr $ra  
 or $at, $zero ; branch delay slot, NOP
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
C.LT.D compares two values. LT is the condition “Less Than”. D implies values of type double. Depending on the result of the comparison, the FCC0 condition bit is either set or cleared.

BC1T checks the FCC0 bit and jumps if the bit is set. T means that the jump is to be taken if the bit is set (“True”). There is also the instruction BC1F which jumps if the bit is cleared (“False”).

Depending on the jump, one of function arguments is placed into $F0.

### 1.25.8 Some constants

It’s easy to find representations of some constants in Wikipedia for IEEE 754 encoded numbers. It’s interesting to know that 0.0 in IEEE 754 is represented as 32 zero bits (for single precision) or 64 zero bits (for double). So in order to set a floating point variable to 0.0 in register or memory, one can use MOV or XOR reg, reg instruction. This is suitable for structures where many variables present of various data types. With usual memset() function one can set all integer variables to 0, all boolean variables to false, all pointers to NULL, and all floating point variables (of any precision) to 0.0.

### 1.25.9 Copying

One may think inertially that FLD/FST instructions must be used to load and store (and hence, copy) IEEE 754 values. Nevertheless, same can be achieved easier by usual MOV instruction, which, of course, copies values bitwisely.

### 1.25.10 Stack, calculators and reverse Polish notation

Now we understand why some old programmable calculators use reverse Polish notation. For example, for addition of 12 and 34 one has to enter 12, then 34, then press “plus” sign.

It’s because old calculators were just stack machine implementations, and this was much simpler than to handle complex parenthesized expressions.

Such a calculator still present in many Unix distributions: dc.

### 1.25.11 80 bits?

Internal numbers representation in FPU — 80-bit. Strange number, because the number not in $2^n$ form. There is a hypothesis that this is probably due to historical reasons—the standard IBM punched card can encode 12 rows of 80 bits. 80: 25 text mode resolution was also popular in past.

If you know better, please a drop email to the author: dennis@yurichev.com.

### 1.25.12 x64

On how floating point numbers are processed in x86-64, read more here: [1.38 on page 431](#).

### 1.25.13 Exercises

- [http://challenges.re/60](http://challenges.re/60)

[129](https://en.wikipedia.org/wiki/Reverse_Polish_notation)
1.26 Arrays

An array is just a set of variables in memory that lie next to each other and that have the same type\textsuperscript{130}.

1.26.1 Simple example

```c
#include <stdio.h>

int main()
{
    int a[20];
    int i;

    for (i=0; i<20; i++)
        a[i]=i*2;

    for (i=0; i<20; i++)
        printf ("a[%d]=%d\n", i, a[i]);

    return 0;
}
```

x86

MSVC

Let's compile:

![MSVC Assembly Code](image)

\textsuperscript{130} AKA "homogeneous container"

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
Nothing very special, just two loops: the first is a filling loop and second is a printing loop. The `shl ecx, 1` instruction is used for value multiplication by 2 in ECX, more about it: [1.24.2 on page 219](#).

80 bytes are allocated on the stack for the array, 20 elements of 4 bytes.
Let's try this example in OllyDbg.

We see how the array gets filled:

each element is 32-bit word of int type and its value is the index multiplied by 2:

![Image of OllyDbg showing array filling](image)

Figure 1.88: OllyDbg: after array filling

Since this array is located in the stack, we can see all its 20 elements there.

**GCC**

Here is what GCC 4.4.1 does:

```
Listing 1.228: GCC 4.4.1

main public

main

var_70 = dword ptr -70h
var_6C = dword ptr -6Ch
var_68 = dword ptr -68h
i_2 = dword ptr -54h
i = dword ptr -4

push ebp
mov ebp, esp
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
...and esp, 0FFFFFFF0h
sub esp, 70h
mov [esp+70h+i], 0 ; i=0
jmp short loc_804840A

loc_80483F7:
mov eax, [esp+70h+i]
mov edx, [esp+70h+i]
add edx, edx ; edx=i*2
mov [esp+eax*4+70h+i_2], edx
add [esp+70h+i], 1 ; i++

loc_804840A:
cmp [esp+70h+i], 13h
jle short loc_80483F7
mov [esp+70h+i], 0
jmp short loc_8048441

loc_804841B:
mov eax, [esp+70h+i]
mov edx, [esp+eax*4+70h+i_2]
mov eax, offset aADD ; "a[%d]=%d\n"
mov [esp+70h+var_68], edx
mov edx, [esp+70h+i]
mov [esp+70h+var_6C], edx
mov [esp+70h+var_70], eax
call _printf
add [esp+70h+i], 1

loc_8048441:
cmp [esp+70h+i], 13h
jle short loc_804841B
mov eax, 0
leave
ret

main endp

By the way, variable $a$ is of type int* (the pointer to int)—you can pass a pointer to an array to another function, but it’s more correct to say that a pointer to the first element of the array is passed (the addresses of rest of the elements are calculated in an obvious way).

If you index this pointer as $a[idx]$, idx is just to be added to the pointer and the element placed there (to which calculated pointer is pointing) is to be returned.

An interesting example: a string of characters like string is an array of characters and it has a type of const char[].

An index can also be applied to this pointer.

And that is why it is possible to write things like “string[i]”—this is a correct C/C++ expression!

**ARM**

  MOV     R1, R4    ; (first printf argument) R1=i
  ADR     R0, aADD  ; "a[%d]=%d\n"
  BL       __2printf
  ADD     R4, R4, #1 ; i=i+1

loc_4C4
  CMP     R4, #20    ; i<20?
  BLT    loc_4B0     ; yes, run loop body again
  MOV     R0, #0     ; value to return
  ADD     SP, SP, #0x50 ; deallocate chunk, allocated for 20 int variables
  LDMFD  SP!, {R4,PC}

int type requires 32 bits for storage (or 4 bytes),
so to store 20 int variables 80 (0x50) bytes are needed. So that is why the SUB SP, SP, #0x50
instruction in the function’s prologue allocates exactly this amount of space in the stack.

In both the first and second loops, the loop iterator i is placed in the R4 register.
The number that is to be written into the array is calculated as i ∗ 2, which is effectively equivalent to
shifting it left by one bit,
so MOV R0, R4,LSL#1 instruction does this.
STR R0, [SP,R4,LSL#2] writes the contents of R0 into the array.
Here is how a pointer to array element is calculated: SP points to the start of the array, R4 is i.
So shifting i left by 2 bits is effectively equivalent to multiplication by 4 (since each array element has a
size of 4 bytes) and then it’s added to the address of the start of the array.
The second loop has an inverse LDR R2, [SP,R4,LSL#2] instruction. It loads the value we need from the
array, and the pointer to it is calculated likewise.

Optimizing Keil 6/2013 (Thumb mode)

_main
  PUSH   {R4,R5,LR}
; allocate place for 20 int variables + one more variable
  SUB     SP, SP, #0x54

; first loop
  MOVS    R0, #0     ; i
  MOV     R5, SP      ; pointer to first array element
loc_1CE
  LSLS    R1, R0, #1  ; R1=i<<1 (same as i*2)
  LSLS    R2, R0, #2  ; R2=i<<2 (same as i*4)
  ADDS    R0, R0, #1  ; i=i+1
  CMP     R0, #20     ; i<20?
  STR     R1, [R5,R2] ; store R1 to *(R5+R2) (same R5+i*4)
  BLT     loc_1CE     ; yes, i<20, run loop body again

; second loop
  MOVS    R4, #0     ; i=0
loc_10C

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!)
LSLS R0, R4, #2 ; R0=i<<2 (same as i*4)
LDR R2, [R5,R0] ; load from *(R5+R0) (same as R5+i*4)
MOV R1, R4
ADR R0, aADD ; "a[%d]=%d\n"
BL __2printf
ADD R4, R4, #1 ; i=i+1
CMP R4, #20 ; i<20?
BLT loc_1DC ; yes, i<20, run loop body again
MOV R0, #0 ; value to return
; deallocate chunk, allocated for 20 int variables + one more variable
ADD SP, SP, #0 x54
POP {R4,R5,PC}

Thumb code is very similar.
Thumb mode has special instructions for bit shifting (like LSLS), which calculates the value to be written into the array and the address of each element in the array as well.

The compiler allocates slightly more space in the local stack, however, the last 4 bytes are not used.

**Non-optimizing GCC 4.9.1 (ARM64)**

Listing 1.229: Non-optimizing GCC 4.9.1 (ARM64)

.LC0:
.string "a[%d]=%d\n"
main:
; save FP and LR in stack frame:
    stp x29, x30, [sp, -112]!
; set stack frame (FP=SP)
    add x29, sp, 0
; setting initial counter variable at 0 (WZR is the register always holding zero):

; jump to loop condition checking code:
    b .L2
.L3:
; load value of "i" variable:
    ldr w0, [x29,108]
; multipliciate it by 2:
    lsl w2, w0, 1
; find a place of an array in local stack:
    add x0, x29, 24
; load 32-bit integer from local stack and sign extend it to 64-bit one:
    ldrsw x1, [x29,108]
; calculate address of element (X0+X1<<2=array address+i*4) and store W2 (i*2) there:
    str w2, [x0,x1,lsl 2]
; increment counter (i):
    ldr w0, [x29,108]
    add w0, w0, 1
    str w0, [x29,108]
.L2:
; check if we finished:
    ldr w0, [x29,108]
    cmp w0, 19
; jump to L3 (loop body begin) if not:
    ble .L3
; second part of the function begins here.
; setting initial counter variable at 0.
; by the way, the same place in the local stack was used for counter,
; because the same local variable (i) is being used as counter.
    str wzr, [x29,108]
    b .L4
.L5:
; calculate array address:
    add x0, x29, 24
; load "i" value:
    ldrsw x1, [x29,108]
; load value from the array at the address (X0+X1<<2 = address of array + i*4)
    ldr w2, [x0,x1,lsl 2]

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com/thanks). Thanks!
load address of the "a[%d]=%d\n" string:
    adrp x0, .LC0
load "i" variable to W1 and pass it to printf() as second argument:
    ldr w1, [x29,108]
    add w0, w0, 1
    str w0, [x29,108]
W2 still contains the value of array element which was just loaded.
; call printf():
    bl printf
increment "i" variable:
    ldr w0, [x29,108]
    add w0, w0, 1
    str w0, [x29,108]

MIPS

The function uses a lot of S- registers which must be preserved, so that’s why its values are saved in the function prologue and restored in the epilogue.

Listing 1.230: Optimizing GCC 4.4.5 (IDA)

main:

var_70 = -0x70
var_68 = -0x68
var_14 = -0x14
var_10 = -0x10
var_C = -0xC
var_8 = -8
var_4 = -4

; function prologue:
    lui $gp, (__gnu_local_gp >> 16)
    addiu $sp, -0x80
    la $gp, (__gnu_local_gp & 0xFFFF)
    sw $ra, 0x80+var_4($sp)
    sw $s3, 0x80+var_8($sp)
    sw $s2, 0x80+var_C($sp)
    sw $s1, 0x80+var_10($sp)
    sw $s0, 0x80+var_14($sp)
    sw $gp, 0x80+var_70($sp)
    addiu $s1, $sp, 0x80+var_68
    move $v1, $s1
    move $v0, $zero

; that value will be used as a loop terminator.
; it was precalculated by GCC compiler at compile stage:
    li $a0, 0x28 # '

loc_34: # CODE XREF: main+3C

; store value into memory:
    sw $v0, 0($v1)

; increase value to be stored by 2 at each iteration:
    addiu $v0, 2

; loop terminator reached?
    bne $v0, $a0, loc_34

; add 4 to address anyway:
    addiu $v1, 4

; array filling loop is ended
; second loop begin

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Something interesting: there are two loops and the first one doesn’t need \textit{i}, it needs only \textit{i} ∗ 2 (increased by 2 at each iteration) and also the address in memory (increased by 4 at each iteration).

So here we see two variables, one (in $V0) increasing by 2 each time, and another (in $V1) — by 4.

The second loop is where \texttt{printf()} is called and it reports the value of \textit{i} to the user, so there is a variable which is increased by 1 each time (in $S0) and also a memory address (in $S1) increased by 4 each time. That reminds us of loop optimizations: \textbf{3.8 on page 497}.

Their goal is to get rid of multiplications.

### 1.26.2 Buffer overflow

#### Reading outside array bounds

So, array indexing is just \texttt{array[index]}. If you study the generated code closely, you’ll probably note the missing index bounds checking, which could check \textit{if it is less than 20}. What if the index is 20 or greater? That’s the one C/C++ feature it is often blamed for.

Here is a code that successfully compiles and works:

```c
#include <stdio.h>

int main()
{
    int a[20];
    int i;
    for (i=0; i<20; i++)
        a[i]=i*2;
    printf ("a[20]=%d\n", a[20]);
    return 0;
};
```

Compilation results (MSVC 2008): (For statistics collecting purposes) if you’ve read this far, please click \texttt{here}. Thanks!
The code produced this result:

```
Listing 1.232: OllyDbg: console output

a[20]=1638280
```

It is just *something* that has been lying in the stack near to the array, 80 bytes away from its first element.
Let's try to find out where did this value come from, using OllyDbg.

Let's load and find the value located right after the last array element:

![OllyDbg screenshot](image)

**Figure 1.89: OllyDbg: reading of the 20th element and execution of printf()**

What is this? Judging by the stack layout, this is the saved value of the EBP register.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's trace further and see how it gets restored:

![Image of OllyDbg interface](image)

**Figure 1.90: OllyDbg: restoring value of EBP**

Indeed, how it could be different? The compiler may generate some additional code to check the index value to be always in the array's bounds (like in higher-level programming languages\(^{131}\)) but this makes the code slower.

**Writing beyond array bounds**

OK, we read some values from the stack illegally, but what if we could write something to it?

Here is what we have got:

```c
#include <stdio.h>

int main()
{
    int a[20];
    int i;
    for (i=0; i<30; i++)
        a[i]=i;
    return 0;
}
```

\(^{131}\)Java, Python, etc.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
And what we get:

Listing 1.233: Non-optimizing MSVC 2008

```assembly
_TEXT SEGMENT
_i$ = -84 ; size = 4
_a$ = -80 ; size = 80
_main PROC
push ebp
mov ebp, esp
sub esp, 84
mov DWORD PTR _i$[ebp], 0
jmp SHORT $LN3@main
$LN2@main:
    mov eax, DWORD PTR _i$[ebp]
    add eax, 1
    mov DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp DWORD PTR _i$[ebp], 30 ; 0000001eH
    jge SHORT $LN1@main
    mov ecx, DWORD PTR _i$[ebp]
    mov edx, DWORD PTR _i$[ebp] ; that instruction is obviously redundant
    mov DWORD PTR _a$[ebp+ecx*4], edx ; ECX could be used as second operand here instead
    jmp SHORT $LN2@main
$LN1@main:
    xor eax, eax
    mov esp, ebp
    pop ebp
    ret 0
_main ENDP
```

The compiled program crashes after running. No wonder. Let’s see where exactly does it crash.
Let's load it into OllyDbg, and trace until all 30 elements are written:

Figure 1.91: OllyDbg: after restoring the value of EBP

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now please keep your eyes on the registers.

EIP is 0x15 now. It is not a legal address for code—at least for win32 code! We got there somehow against our will. It is also interesting that the EBP register contain 0x14, ECX and EDX contain 0x1D.

Let’s study stack layout a bit more.

After the control flow has been passed to main(), the value in the EBP register was saved on the stack. Then, 84 bytes were allocated for the array and the i variable. That’s (20+1)*sizeof(int). ESP now points to the i variable in the local stack and after the execution of the next PUSH something, something is appearing next to i.

That’s the stack layout while the control is in main():

<table>
<thead>
<tr>
<th>ESP</th>
<th>4 bytes allocated for i variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP+4</td>
<td>80 bytes allocated for a[20] array</td>
</tr>
<tr>
<td>ESP+84</td>
<td>saved EBP value</td>
</tr>
<tr>
<td>ESP+88</td>
<td>return address</td>
</tr>
</tbody>
</table>

a[19]=something statement writes the last int in the bounds of the array (in bounds so far!).

a[20]=something statement writes something to the place where the value of EBP is saved.

Please take a look at the register state at the moment of the crash. In our case, 20 has been written in the 20th element. At the function end, the function epilogue restores the original EBP value. (20 in decimal

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
is 0x14 in hexadecimal). Then RET gets executed, which is effectively equivalent to POP EIP instruction. The RET instruction takes the return address from the stack (that is the address in CRT, which has called main()), and 21 is stored there (0x15 in hexadecimal). The CPU traps at address 0x15, but there is no executable code there, so exception gets raised.

Welcome! It is called a buffer overflow\textsuperscript{132}.

Replace the int array with a string (char array), create a long string deliberately and pass it to the program, to the function, which doesn't check the length of the string and copies it in a short buffer, and you'll able to point the program to an address to which it must jump. It's not that simple in reality, but that is how it emerged. Classic article about it: [Aleph One, Smashing The Stack For Fun And Profit, (1996)]\textsuperscript{133}.

**GCC**

Let's try the same code in GCC 4.4.1. We get:

```c
public main
main proc near
a = dword ptr -54h
i = dword ptr -4
push  ebp
mov  ebp, esp
sub  esp, 60h ; 96
mov  [%ebp+1], 0
jmp  short loc_80483D1
loc_80483C3:
mov  eax, [%ebp+1]
mov  edx, [%ebp+1]
mov  [%ebp+eax*4+a], edx
add  [%ebp+1], 1
loc_80483D1:
cmp  [%ebp+1], 1Dh
jle  short loc_80483C3
mov  eax, 0
leave
retn
main endp
```

Running this in Linux will produce: Segmentation fault.

If we run this in the GDB debugger, we get this:

```
(gdb) r
Starting program: /home/dennis/RE/1
Program received signal SIGSEGV, Segmentation fault.

The register values are slightly different than in win32 example, since the stack layout is slightly different too.

### 1.26.3 Buffer overflow protection methods

There are several methods to protect against this scourge, regardless of the C/C++ programmers’ negligence. MSVC has options like:

```
/RTCs Stack Frame runtime checking
/GZ Enable stack checks (/RTCs)
```

One of the methods is to write a random value between the local variables in stack at function prologue and to check it in function epilogue before the function exits. If value is not the same, do not execute the last instruction RET, but stop (or hang). The process will halt, but that is much better than a remote attack to your host.

This random value is called a “canary” sometimes, it is related to the miners’ canary\(^{135}\), they were used by miners in the past days in order to detect poisonous gases quickly.

Canaries are very sensitive to mine gases, they become very agitated in case of danger, or even die.

If we compile our very simple array example (1.26.1 on page 268) in MSVC with RTC1 and RTCs option, you can see a call to \(_\text{RTC\_CheckStackVars}\@8\) a function at the end of the function that checks if the “canary” is correct.

Let’s see how GCC handles this. Let’s take an `alloca()` (1.9.2 on page 34) example:

```c
#include _GNU_  
#include <alloca.h> // GCC  
#else  
#include <malloc.h> // MSVC  
#endif  
#include <stdio.h>

void f()  
{  
   char *buf=(char*)alloca (600);  
   #ifdef _GNU_  
   #if defined _GNU_  
   snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3);  // GCC  
   #else  
   snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3);  // MSVC  
   #endif  
   puts (buf);  
}
```

By default, without any additional options, GCC 4.7.3 inserts a “canary” check into the code:

```
.LC0:  
   .string "hi! %d, %d, %d\n"

f:  
   push   ebp  
   mov    ebp, esp  
   push   ebx  
   sub    esp, 676  
   lea    ebx, [esp+39]  
   and    ebx, -16  
   mov    DWORD PTR [esp+20], 3  
   mov    DWORD PTR [esp+16], 2  
   mov    DWORD PTR [esp+12], 1  
   mov    DWORD PTR [esp+8], OFFSET FLAT:.LC0 ; "hi! %d, %d, %d\n"  
   mov    DWORD PTR [esp+4], 600
```

\(^{135}\)wikipedia.org/wiki/Domestic_canary#Miner\'s_canary

(For statistics collecting purposes) if you've read this far, please click [here](http://). Thanks!
The random value is located in gs:20. It gets written on the stack and then at the end of the function the value in the stack is compared with the correct “canary” in gs:20. If the values are not equal, the __stack_chk_fail function is called and we can see in the console something like that (Ubuntu 13.04 x86):

```c
*** buffer overflow detected ***: ./2_1 terminated

Aborted (core dumped)

gs is the so-called segment register. These registers were used widely in MS-DOS and DOS-extenders times. Today, its function is different.

To say it briefly, the gs register in Linux always points to the TLS136 (6.2 on page 741)—some information specific to thread is stored there. By the way, in win32 the fs register plays the same role, pointing to TIB137 138.

More information can be found in the Linux kernel source code (at least in 3.11 version), in arch/x86/include/asm/stackprotection.h this variable is described in the comments.

Let's get back to our simple array example (1.26.1 on page 268), again, now we can see how LLVM checks the correctness of the “canary”:

```assembly
_main
var_64  = -0x64
var_60  = -0x60
var_5C  = -0x5C
var_58  = -0x58
var_54  = -0x54
var_50  = -0x50
var_4C  = -0x4C
var_48  = -0x48
var_44  = -0x44
var_40  = -0x40
var_3C  = -0x3C
var_38  = -0x38
var_34  = -0x34
var_30  = -0x30
var_2C  = -0x2C
var_28  = -0x28
var_24  = -0x24
var_20  = -0x20
var_1C  = -0x1C
var_18  = -0x18
canary  = -0x14
var_10  = -0x10

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
First of all, as we see, LLVM “unrolled” the loop and all values were written into an array one-by-one, pre-calculated, as LLVM concluded it can work faster. By the way, instructions in ARM mode may help to do this even faster, and finding this could be your homework.

At the function end we see the comparison of the “canaries”—the one in the local stack and the correct one, to which \( R^8 \) points.

If they are equal to each other, a 4-instruction block is triggered by ITTTT EQ, which contains writing 0 in \( R^0 \), the function epilogue and exit. If the “canaries” are not equal, the block being skipped, and the jump to \( ___stack_chk_fail \) function will occur, which, perhaps will halt execution.

### 1.26.4 One more word about arrays

Now we understand why it is impossible to write something like this in C/C++ code:

```c
void f(int size) {
    int a[size];
    ...
}
```

That’s just because the compiler must know the exact array size to allocate space for it in the local stack layout on at the compiling stage.

If you need an array of arbitrary size, allocate it by using malloc(), then access the allocated memory block as an array of variables of the type you need.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Or use the C99 standard feature [ISO/IEC 9899:TC3 (C C99 standard), (2007)6.7.5/2], and it works like `alloca()` (1.9.2 on page 34) internally.

It's also possible to use garbage collecting libraries for C.

And there are also libraries supporting smart pointers for C++.

### 1.26.5 Array of pointers to strings

Here is an example for an array of pointers.

```
#include <stdio.h>

const char* month1[] =
{
    "January", "February", "March", "April",
    "May", "June", "July", "August",
    "September", "October", "November", "December"
};

// in 0..11 range
const char* get_month1 (int month)
{
    return month1[month];
}
```

### x64

```
_DATA SEGMENT

$SG3130 DB 'September', 00H
$SG3156 DB '%s', 0aH, 00H
$SG3131 DB 'October', 00H
$SG3132 DB 'November', 00H
$SG3133 DB 'December', 00H
_DATA ENDS

month$ = 8
get_month1 PROC
    movsx  rax, ecx
    lea   rcx, OFFSET FLAT:month1
    mov   rax, QWORD PTR [rcx+rax*8]
    ret
get_month1 ENDP
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The code is very simple:

- The first MOVSDX instruction copies a 32-bit value from ECX (where \textit{month} argument is passed) to RAX with sign-extension (because the \textit{month} argument is of type \texttt{int}).

The reason for the sign extension is that this 32-bit value is to be used in calculations with other 64-bit values.

Hence, it has to be promoted to 64-bit\textsuperscript{139}.

- Then the address of the pointer table is loaded into RCX.

- Finally, the input value (\textit{month}) is multiplied by 8 and added to the address. Indeed: we are in a 64-bit environment and all address (or pointers) require exactly 64 bits (or 8 bytes) for storage. Hence, each table element is 8 bytes wide. And that’s why to pick a specific element, \textit{month} \times 8 bytes has to be skipped from the start. That’s what MOV does. In addition, this instruction also loads the element at this address. For 1, an element would be a pointer to a string that contains “February”, etc.

Optimizing GCC 4.9 can do the job even better\textsuperscript{140}:

\begin{verbatim}
  Listing 1.237: Optimizing GCC 4.9 x64
  movsx rdi, edi
  mov rax, QWORD PTR month1[0+rdi*8]
  ret
\end{verbatim}

\textbf{32-bit MSVC}

Let’s also compile it in the 32-bit MSVC compiler:

\begin{verbatim}
  Listing 1.238: Optimizing MSVC 2013 x86
  _month$ = 8
  _get_month1 PROC
    mov eax, DWORD PTR _month$[esp-4]
    mov eax, DWORD PTR _month1[eax*4]
    ret
  _get_month1 ENDP
\end{verbatim}

The input value does not need to be extended to 64-bit value, so it is used as is.
And it’s multiplied by 4, because the table elements are 32-bit (or 4 bytes) wide.

\textbf{32-bit ARM}

\textbf{ARM in ARM mode}

\begin{verbatim}
  Listing 1.239: Optimizing Keil 6/2013 (ARM mode)
  get_month1 PROC
    LDR r1,|L0.100|
    LDR r0,|[r1,r0,LSL #2]
    BX lr
  ENDP
  |L0.100|
    DCD ||.data||
    DCB "January",0
    DCB "February",0
    DCB "March",0
    DCB "April",0
    DCB "May",0
\end{verbatim}

\textsuperscript{139}It is somewhat weird, but negative array index could be passed here as \textit{month} (negative array indices will have been explained later: 3.20 on page 600). And if this happens, the negative input value of \texttt{int} type is sign-extended correctly and the corresponding element before table is picked. It is not going to work correctly without sign-extension.

\textsuperscript{140}“0+” was left in the listing because GCC assembler output is not tidy enough to eliminate it. It’s \textit{displacement}, and it’s zero here.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The address of the table is loaded in R1.

All the rest is done using just one LDR instruction.

Then input value \texttt{month} is shifted left by 2 (which is the same as multiplying by 4), then added to R1 (where the address of the table is) and then a table element is loaded from this address.

The 32-bit table element is loaded into R0 from the table.

**ARM in Thumb mode**

The code is mostly the same, but less dense, because the \texttt{LSL} suffix cannot be specified in the \texttt{LDR} instruction here:

```assembly
get_month1 PROC
    LLSL r0, r0, #2
    LDR r1, [L0, .64]
    LDR r0, [r1, r0]
    BX lr
ENDP
```

**ARM64**

Listing 1.240: Optimizing GCC 4.9 ARM64

```assembly
get_month1:
    adrp x1, .LANCHOR0
    add x1, x1, :lo12:.LANCHOR0
    ldr x0, [x1, w0, sxtw 3]
    ret

.LANCHOR0 = .+ 0
.type month1, %object
.size month1, 96
month1:
    .xword .LC2
    .xword .LC3
    .xword .LC4
    .xword .LC5
    .xword .LC6
    .xword .LC7
    .xword .LC8
    .xword .LC9
    .xword .LC10
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The address of the table is loaded in X1 using ADRP/ADD pair.

Then corresponding element is picked using just one LDR, which takes W0 (the register where input argument month is), shifts it 3 bits to the left (which is the same as multiplying by 8), sign-extends it (this is what “sxtw” suffix implies) and adds to X0. Then the 64-bit value is loaded from the table into X0.

MIPS

Array overflow

Our function accepts values in the range of 0..11, but what if 12 is passed? There is no element in table at this place.

So the function will load some value which happens to be there, and return it.

Soon after, some other function can try to get a text string from this address and may crash.

Let's compile the example in MSVC for win64 and open it in IDA to see what the linker has placed after the table:

```
Listing 1.242: Executable file in IDA

off_140011000 dq offset aJanuary_1 ; DATA XREF: .text:0000000140001003
            ; "January"
            dq offset aFebruary_1  ; "February"
            dq offset aMarch_1     ; "March"
            dq offset aApril_1     ; "April"
            dq offset aMay_1       ; "May"
            dq offset aJune_1      ; "June"
            dq offset aJuly_1      ; "July"
            dq offset aAugust_1    ; "August"
            dq offset aSeptember_1 ; "September"
            dq offset aOctober_1   ; "October"
            dq offset aNovember_1  ; "November"
            dq offset aDecember_1  ; "December"

aJanuary_1 db 'January',0 ; DATA XREF: sub_140001020+4
            ; .data:off_140011000
aFebruary_1 db 'February',0 ; DATA XREF: .data:0000000140011008
align 4
aMarch_1 db 'March',0 ; DATA XREF: .data:0000000140011010
align 4
aApril_1 db 'April',0 ; DATA XREF: .data:0000000140011018
```

Month names are came right after.

Our program is tiny, so there isn't much data to pack in the data segment, so it just the month names. But it has to be noted that there might be really anything that linker has decided to put by chance.

So what if 12 is passed to the function? The 13th element will be returned.

Let's see how the CPU treats the bytes there as a 64-bit value:

```
Listing 1.243: Executable file in IDA

off_140011000 dq offset qword_140011060 ; DATA XREF: .text:0000000140001003
            ; "January"
            dq offset aFebruary_1  ; "February"
            dq offset aMarch_1     ; "March"
            dq offset aApril_1     ; "April"
            dq offset aMay_1       ; "May"
            dq offset aJune_1      ; "June"
            dq offset aJuly_1      ; "July"
            dq offset aAugust_1    ; "August"
            dq offset aSeptember_1 ; "September"
            dq offset aOctober_1   ; "October"
            dq offset aNovember_1  ; "November"
            dq offset aDecember_1  ; "December"

qword_140011060 dq 797261756E614Ah ; DATA XREF: sub_140001020+4
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
And this is 0x797261756E614A.

Soon after, some other function (presumably, one that processes strings) may try to read bytes at this address, expecting a C-string there.

Most likely it is about to crash, because this value doesn’t look like a valid address.

**Array overflow protection**

If something can go wrong, it will

Murphy’s Law

It’s a bit naïve to expect that every programmer who use your function or library will never pass an argument larger than 11.

There exists the philosophy that says “fail early and fail loudly” or “fail-fast”, which teaches to report problems as early as possible and halt.

One such method in C/C++ is assertions.

We can modify our program to fail if an incorrect value is passed:

```c
const char* get_month1_checked (int month)
{
    assert (month<12);
    return month1[month];
};
```

The assertion macro checks for valid values at every function start and fails if the expression is false.

```c
Listing 1.245: Optimizing MSVC 2013 x64

$SG3143 DB 'm', 00H, 'o', 00H, 'n', 00H, 't', 00H, 'h', 00H, '.', 00H
DB 'c', 00H, 00H, 00H
$SG3144 DB 'm', 00H, 'o', 00H, 'n', 00H, 't', 00H, 'h', 00H, '<', 00H
DB '1', 00H, '2', 00H, 00H, 00H

month$ = 48
get_month1_checked PROC
$LN5:
    push rbx
    sub rsp, 32
    movsx rbx, ecx
    cmp ebx, 12
    jl SHORT $LN3@get_month1
    lea rdx, OFFSET FLAT:$SG3143
    lea rcx, OFFSET FLAT:$SG3144
    mov r8d, 29
    call _wassert
$LN3@get_month1:
    lea rcx, OFFSET FLAT:month1
    mov rax, QWORD PTR [rcx+rbx*8]
    add rsp, 32
    pop rbx
    ret 0
get_month1_checked ENDP
```

In fact, assert() is not a function, but macro. It checks for a condition, then passes also the line number and file name to another function which reports this information to the user.

Here we see that both file name and condition are encoded in UTF-16. The line number is also passed (it’s 29).
This mechanism is probably the same in all compilers. Here is what GCC does:

Listing 1.246: Optimizing GCC 4.9 x64

```
.LC1:
    .string "month.c"
.LC2:
    .string "month<12"

get_month1_checked:
    cmp     edi, 11
    jg      .L6
    movsx   rdi, edi
    mov     rax, QWORD PTR month1[0+rdi*8]
    ret

.L6:
    push    rax
    mov     ecx, OFFSET FLAT:__PRETTY_FUNCTION__.2423
    mov     edx, 29
    mov     esi, OFFSET FLAT:.LC1
    mov     edi, OFFSET FLAT:.LC2
    call    __assert_fail

__PRETTY_FUNCTION__.2423:
    .string "get_month1_checked"
```

So the macro in GCC also passes the function name for convenience.

Nothing is really free, and this is true for the sanitizing checks as well. They make your program slower, especially if the assert() macros used in small time-critical functions. So MSVC, for example, leaves the checks in debug builds, but in release builds they all disappear. Microsoft Windows NT kernels come in “checked” and “free” builds.

The first has validation checks (hence, “checked”), the second one doesn’t (hence, “free” of checks). Of course, “checked” kernel works slower because of all these checks, so it is usually used only in debug sessions.

**Accessing specific character**

An array of pointers to strings can be accessed like this:

```
#include <stdio.h>

const char* month[] =
{
    "January", "February", "March", "April",
    "May", "June", "July", "August",
    "September", "October", "November", "December"
};

int main()
{
    // 4th month, 5th character:
    printf ("%c\n", month[3][4]);
}
```

... since month[3] expression has a `const char*` type. And then, 5th character is taken from that expression by adding 4 bytes to its address.

By the way, arguments list passed to main() function has the same data type:

```
#include <stdio.h>

int main(int argc, char *argv[])
{
    printf ("3rd argument, 2nd character: %c\n", argv[3][1]);
}
```

(For statistics collecting purposes) if you’ve read this far, please click [here](https://msdn.microsoft.com/en-us/library/windows/hardware/ff543450(v=vs.85).aspx). Thanks!
It’s very important to understand, that, despite similar syntax, this is different from two-dimensional arrays, which we will consider later.

Another important thing to notice: strings to be addressed must be encoded in a system, where each character occupies single byte, like ASCII and extended ASCII. UTF-8 wouldn’t work here.

1.26.6 Multidimensional arrays

Internally, a multidimensional array is essentially the same thing as a linear array. Since the computer memory is linear, it is an one-dimensional array. For convenience, this multi-dimensional array can be easily represented as one-dimensional.

For example, this is how the elements of the 3x4 array are placed in one-dimensional array of 12 cells:

<table>
<thead>
<tr>
<th>Offset in memory</th>
<th>array element</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[0][0]</td>
</tr>
<tr>
<td>1</td>
<td>[0][1]</td>
</tr>
<tr>
<td>2</td>
<td>[0][2]</td>
</tr>
<tr>
<td>3</td>
<td>[0][3]</td>
</tr>
<tr>
<td>4</td>
<td>[1][0]</td>
</tr>
<tr>
<td>5</td>
<td>[1][1]</td>
</tr>
<tr>
<td>6</td>
<td>[1][2]</td>
</tr>
<tr>
<td>7</td>
<td>[1][3]</td>
</tr>
<tr>
<td>8</td>
<td>[2][0]</td>
</tr>
<tr>
<td>9</td>
<td>[2][1]</td>
</tr>
<tr>
<td>10</td>
<td>[2][2]</td>
</tr>
<tr>
<td>11</td>
<td>[2][3]</td>
</tr>
</tbody>
</table>

Table 1.3: Two-dimensional array represented in memory as one-dimensional

Here is how each cell of 3*4 array are placed in memory:

```
0  1  2  3
4  5  6  7
8  9 10 11
```

Table 1.4: Memory addresses of each cell of two-dimensional array

So, in order to calculate the address of the element we need, we first multiply the first index by 4 (array width) and then add the second index. That’s called row-major order, and this method of array and matrix representation is used in at least C/C++ and Python. The term row-major order in plain English language means: “first, write the elements of the first row, then the second row ...and finally the elements of the last row”.

Another method for representation is called column-major order (the array indices are used in reverse order) and it is used at least in Fortran, MATLAB and R. column-major order term in plain English language means: “first, write the elements of the first column, then the second column ...and finally the elements of the last column”.

Which method is better?

In general, in terms of performance and cache memory, the best scheme for data organization is the one, in which the elements are accessed sequentially.

So if your function accesses data per row, row-major order is better, and vice versa.

Two-dimensional array example

We are going to work with an array of type char, which implies that each element requires only one byte in memory.

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Row filling example

Let's fill the second row with these values 0..3:

Listing 1.247: Row filling example

```c
#include <stdio.h>
char a[3][4];
int main()
{
    int x, y;
    // clear array
    for (x=0; x<3; x++)
        for (y=0; y<4; y++)
            a[x][y]=0;
    // fill second row by 0..3:
    for (y=0; y<4; y++)
        a[1][y]=y;
}
```

All three rows are marked with red. We see that second row now has values 0, 1, 2 and 3:

![OllyDbg: array is filled](image)

Column filling example

Let's fill the third column with values: 0..2:

Listing 1.248: Column filling example

```c
#include <stdio.h>
char a[3][4];
int main()
{
    int x, y;
    // clear array
    for (x=0; x<3; x++)
        for (y=0; y<4; y++)
            a[x][y]=0;
    // fill third column by 0..2:
    for (x=0; x<3; x++)
        a[x][2]=x;
}
```

The three rows are also marked in red here.

We see that in each row, at third position these values are written: 0, 1 and 2.

![OllyDbg: array is filled](image)
Access two-dimensional array as one-dimensional

We can be easily assured that it's possible to access a two-dimensional array as one-dimensional array in at least two ways:

```c
#include <stdio.h>

char a[3][4];

char get_by_coordinates1 (char array[3][4], int a, int b)
{
    return array[a][b];
};

char get_by_coordinates2 (char *array, int a, int b)
{
    // treat input array as one-dimensional
    // 4 is array width here
    return array[a*4+b];
};

char get_by_coordinates3 (char *array, int a, int b)
{
    // treat input array as pointer,
    // calculate address, get value at it
    // 4 is array width here
    return *(array+a*4+b);
};

int main()
{
    a[2][3]=123;
    printf ("%d\n", get_by_coordinates1(a, 2, 3));
    printf ("%d\n", get_by_coordinates2(a, 2, 3));
    printf ("%d\n", get_by_coordinates3(a, 2, 3));
};
```

Compile\(^{143}\) and run it: it shows correct values.

What MSVC 2013 did is fascinating, all three routines are just the same!

Listing 1.249: Optimizing MSVC 2013 x64

```
array$ = 8
a$ = 16
b$ = 24
get_by_coordinates3 PROC
; RCX=address of array
; RDX=a
; R8=b
    movsx   rax, r8d
 ; EAX=b
    movsx   r9, edx
 ; R9=a
    add     rax, rcx
 ; RAX=b+address of array
    movzx   eax, BYTE PTR [rax+r9*4]
 ; AL=load byte at address RAX+R9*4=b+address of array+a*4=address of array+a*4+b
ret
get_by_coordinates3 ENDP
```

\(^{143}\)This program is to be compiled as a C program, not C++, save it to a file with .c extension to compile it using MSVC

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
get_by_coordinates2 ENDP

; RDI=address of array
; RSI=a
; RDX=b

gcc also generates equivalent routines, but slightly different:

Listing 1.250: Optimizing GCC 4.9 x64

get_by_coordinates1:
; sign-extend input 32-bit int values "a" and "b" to 64-bit ones
    movsx rsi, esi
    movsx rdx, edx
    lea rax, [rdi+rsi*4]
; RAX=RDRI+RSI*4=address of array+a*4
    movzx eax, BYTE PTR [rax+rdx]
; AL=load byte at address RAX+RDX=address of array+a*4+b
    ret

gcc also generates equivalent routines, but slightly different:

Listing 1.250: Optimizing GCC 4.9 x64

get_by_coordinates1:
; sign-extend input 32-bit int values "a" and "b" to 64-bit ones
    movsx rsi, esi
    movsx rdx, edx
    lea rax, [rdi+rsi*4]
; RAX=RDRI+RSI*4=address of array+a*4
    movzx eax, BYTE PTR [rax+rdx]
; AL=load byte at address RAX+RDX=address of array+a*4+b
    ret

gcc also generates equivalent routines, but slightly different:

Listing 1.250: Optimizing GCC 4.9 x64

get_by_coordinates2:
    lea eax, [rdx+rsi*4]
; RAX=RXD+RSI*4=b+a*4
    cdqe
    movzx eax, BYTE PTR [rdi+rax]
; AL=load byte at address RDI+RAX=address of array+b+a*4
    ret

gcc also generates equivalent routines, but slightly different:

Listing 1.250: Optimizing GCC 4.9 x64

get_by_coordinates3:
    sal esi, 2
; ESI=a<<2=a*4
; sign-extend input 32-bit int values "a*4" and "b" to 64-bit ones
    movsx rdx, edx
    movsx rsi, esi
    add rdi, rsi
; RDI=RDRI+RSI=address of array+a*4
    movzx eax, BYTE PTR [rdi+rdx]
; AL=load byte at address RDI+RDX=address of array+a*4+b
    ret

Three-dimensional array example

It's the same for multidimensional arrays.
Now we are going to work with an array of type int: each element requires 4 bytes in memory.
Let's see:

Listing 1.251: simple example

#include <stdio.h>

int a[10][20][30];

void insert(int x, int y, int z, int value)
{
    a[x][y][z]=value;
};
We get (MSVC 2010):

Listing 1.252: MSVC 2010

```
_DATA SEGMENT
COMM   _a:DWORD:01770H
_DATA ENDS
PUBLIC _insert
_TEXT SEGMENT
_x$ = 8 ; size = 4
_y$ = 12 ; size = 4
_z$ = 16 ; size = 4
_value$ = 20 ; size = 4
_insert PROC
    push ebp
    mov ebp, esp
    push ebx
    mov ebx, [ebp+x]
    mov eax, [ebp+y]
    mov ecx, [ebp+z]
    lea edx, [eax+eax] ; edx=y*2
    mov eax, edx ; eax=y*2
    shl eax, 4 ; eax=(y*2)<<4 = y*2*16 = y*32
    sub eax, edx ; eax=y*32 - y*2=y*30
    imul edx, ebx, 600 ; edx=x*600
    add eax, edx ; eax=ax+edx=x*30 + x*600
    lea edx, [eax+ecx] ; edx=x*30 + x*600 + z
    mov eax, [ebp+value]
    mov dword ptr ds:a[edx*4], eax ; *(a+edx*4)=value
    pop ebx
    pop ebp
    ret
_insert ENDP
_TEXT ENDS
```

Nothing special. For index calculation, three input arguments are used in the formula \( address = 600 \cdot 4 \cdot x + 30 \cdot 4 \cdot y + 4z \), to represent the array as multidimensional. Do not forget that the \textit{int} type is 32-bit (4 bytes), so all coefficients must be multiplied by 4.

Listing 1.253: GCC 4.4.1

```
public insert
insert proc near
x = dword ptr 8
y = dword ptr 0Ch
z = dword ptr 10h
value = dword ptr 14h
    push ebp
    mov ebp, esp
    push ebx
    mov ebx, [ebp+x]
    mov eax, [ebp+y]
    mov ecx, [ebp+z]
    lea edx, [eax+eax] ; edx=y*2
    mov eax, edx ; eax=y*2
    shl eax, 4 ; eax=(y*2)<<4 = y*2*16 = y*32
    sub eax, edx ; eax=y*32 - y*2=y*30
    imul edx, ebx, 600 ; edx=x*600
    add eax, edx ; eax=ax+edx=x*30 + x*600
    lea edx, [eax+ecx] ; edx=x*30 + x*600 + z
    mov eax, [ebp+value]
    mov dword ptr ds:a[edx*4], eax ; *(a+edx*4)=value
    pop ebx
    pop ebp
    ret
_insert endp
```

The GCC compiler does it differently.

For one of the operations in the calculation \((30y)\), GCC produces code without multiplication instructions. This is how it done: \((y + y) \ll 4 - (y + y) = (2y) \ll 4 - 2 \cdot 16 \cdot y - 2y = 32y - 2y = 30y\). Thus, for the 30y calculation, only one addition operation, one bitwise shift operation and one subtraction operation are used. This works faster.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.254: Non-optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```assembly
_insert

value = -0x10
z = -0xC
y = -8
x = -4;

; allocate place in local stack for 4 values of int type
SUB SP, SP, #0x10
MOV R9, 0xFC2; a
ADD R9, PC
LDR.W R9, [R9]; get pointer to array
STR R0, [SP,#0x10+x]
STR R1, [SP,#0x10+y]
STR R2, [SP,#0x10+z]
STR R3, [SP,#0x10+value]
LDR R0, [SP,#0x10+value]
LDR R1, [SP,#0x10+z]
LDR R2, [SP,#0x10+y]
LDR R3, [SP,#0x10+x]
MOV R12, 2400
MUL.W R3, R3, R12
ADD R9, PC
LDR.W R9, [R9]; R9 = pointer to an array
MLA.W R0, R0, R12, R9
ADD R9, R0
ADD R0, R9, R1, R2; R1 = y<<2
ADD R1, R2
STR R0, [R1]; R1 - address of array element
; deallocate chunk in local stack, allocated for 4 values of int type
ADD SP, SP, #0x10
BX LR
```

Non-optimizing LLVM saves all variables in local stack, which is redundant.
The address of the array element is calculated by the formula we already saw.

**ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)**

Listing 1.255: Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```assembly
_insert

MOV.W R9, #0x10FC
MOV.W R12, #2400
MOV.W R9, #0
RSB.W R1, R1, R1,LSL#4; R1 = y<<4 - y = y*16 - y = y*15
ADD R9, PC
LDR.W R9, [R9]; R9 = pointer to an array
MLA.W R0, R0, R12, R9; R0 = x, R12 - 2400, R9 - pointer to a. R0=x*2400 + ptr to a
ADD.W R0, R0, R1,LSL#3; R0 = R0+R1<<3 = R0+R1*8 = x*2400 + ptr to a + y*15*8 =
                    ; ptr to a + y*30*4 + x*600*4
STR.W R3, [R0,R2,LSL#2]; R2 - z, R3 - value. address=R0+z*4 =
                    ; ptr to a + y*30*4 + x*600*4 + z*4
BX LR
```

The tricks for replacing multiplication by shift, addition and subtraction which we already saw are also present here.
Here we also see a new instruction for us: RSB (Reverse Subtract).
It works just as SUB, but it swaps its operands with each other before execution. Why? SUB and RSB are instructions, to the second operand of which shift coefficient may be applied: (LSL#4).
But this coefficient can be applied only to second operand.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
That’s fine for commutative operations like addition or multiplication (operands may be swapped there without changing the result).

But subtraction is a non-commutative operation, so RSB exist for these cases.

**MIPS**

My example is tiny, so the GCC compiler decided to put the *a* array into the 64KiB area addressable by the Global Pointer.

```mips
Listing 1.256: Optimizing GCC 4.4.5 (IDA)

insert:
; $a0=x
; $a1=y
; $a2=z
; $a3=value
    sll $v0, $a0, 5
; $v0 = $a0<<5 = x*32
    sll $a0, 3
; $a0 = $a0<<3 = x*8
    addu $a0, $v0
; $a0 = $a0+$v0 = x*8+x*32 = x*40
    sll $v1, $a1, 5
; $v1 = $a1<<5 = y*32
    sll $v0, $a0, 4
; $v0 = $a0<<4 = x*40*16 = x*640
    sll $a1, 1
; $a1 = $a1<<1 = y*2
    subu $a1, $v1, $a1
; $a1 = $v1-$a1 = y*32-y*2 = y*30
    subu $a0, $v0, $a0
; $a0 = $v0-$a0 = x*640-x*40 = x*600
    la $gp, __gnu_local_gp
    addu $a0, $a1, $a0
; $a0 = $a1+$a0 = y*30+x*600
    addu $a0, $a2
; $a0 = $a0+$a2 = y*30+x*600+z
; load address of table:
    lw $v0, (a & 0xFFFF)($gp)
; multiply index by 4 to seek array element:
    sll $a0, 2
; sum up multiplied index and table address:
    addu $a0, $v0, $a0
; store value into table and return:
    jr $ra
    sw $a3, 0($a0)
    .comm a:0x1770
```

**Getting dimensions of multidimensional array**

Any string processing function, if an array of characters passed to it, can’t deduce a size of the input array. Likewise, if a function processes 2D array, only one dimension can be deduced.

For example:

```c
int get_element(int array[10][20], int x, int y)
{
    return array[x][y];
}

int main()
{
    int array[10][20];
    get_element(array, 4, 5);
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
... if compiled (by any compiler) and then decompiled by Hex-Rays:

```c
int get_element(int *array, int x, int y)
{
  return array[20 * x + y];
}
```

There is no way to find a size of the first dimension. If x value passed is too big, buffer overflow would occur, an element from some random place of memory would be read.

And 3D array:

```c
int get_element(int array[10][20][30], int x, int y, int z)
{
  return array[x][y][z];
};
int main()
{
  int array[10][20][30];
  get_element(array, 4, 5, 6);
};

Hex-Rays:

```c
int get_element(int *array, int x, int y, int z)
{
  return array[600 * x + z + 30 * y];
}
```

Again, sizes of only two of 3 dimensions can be deduced.

**More examples**

The computer screen is represented as a 2D array, but the video-buffer is a linear 1D array. We talk about it here: 8.12.2 on page 888.

Another example in this book is Minesweeper game: it's field is also two-dimensional array: 8.3 on page 802.

### 1.26.7 Pack of strings as a two-dimensional array

Let's revisit the function that returns the name of a month: listing.1.235.

As you see, at least one memory load operation is needed to prepare a pointer to the string that's the month's name.

Is it possible to get rid of this memory load operation?

In fact yes, if you represent the list of strings as a two-dimensional array:

```c
#include <stdio.h>
#include <assert.h>

const char month2[12][10]=
{
  { 'J','a','n','u','a','r','y', 0, 0, 0 },
  { 'F','e','b','r','u','a','r','y', 0, 0, 0 },
  { 'M','a','r','c','h', 0, 0, 0, 0 },
  { 'A','p','r','i','l', 0, 0, 0, 0 },
  { 'M','a','y', 0, 0, 0, 0, 0 },
  { 'J','u','n','e', 0, 0, 0, 0, 0 },
  { 'J','u','l','y', 0, 0, 0, 0, 0 },
  { 'A','u','g','u','s','t', 0, 0, 0, 0 },
  { 'S','e','p','t','e','m','b','e','r', 0 , 0, 0, 0 }
};
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Here is what we’ve get:

Listing 1.257: Optimizing MSVC 2013 x64

```plaintext
month2 DB 04aH
  DB 061H
  DB 06eH
  DB 075H
  DB 061H
  DB 072H
  DB 079H
  DB 00H
  DB 00H
...

get_month2 PROC
  ; sign-extend input argument and promote to 64-bit value
  movsxd rax, ecx
  lea rcx, QWORD PTR [rax+rcx*4]
  ; RCX=month+month*4=month*5
  lea rax, OFFSET FLAT:month2
  ; RAX=pointer to table
  lea rax, QWORD PTR [rax+rcx*2]
  ; RAX=pointer to table + RCX*2=pointer to table + month*5*2=pointer to table + month*10
  ret 0
get_month2 ENDP
```

There are no memory accesses at all.

All this function does is to calculate a point at which the first character of the name of the month is: `pointer_to_the_table + month * 10`.

There are also two LEA instructions, which effectively work as several MUL and MOV instructions.

The width of the array is 10 bytes.

Indeed, the longest string here—“September”—is 9 bytes, and plus the terminating zero is 10 bytes.

The rest of the month names are padded by zero bytes, so they all occupy the same space (10 bytes).

Thus, our function works even faster, because all string start at an address which can be calculated easily.

Optimizing GCC 4.9 can do it even shorter:

Listing 1.258: Optimizing GCC 4.9 x64

```plaintext
movsx rdi, edi
lea rax, [rdi+rdi*4]
lea rax, month2[rax+rax]
ret
```

LEA is also used here for multiplication by 10.

Non-optimizing compilers do multiplication differently.

Listing 1.259: Non-optimizing GCC 4.9 x64

```plaintext
get_month2:
push rbp
mov rbp, rsp
mov DWORD PTR [rbp-4], edi
mov eax, DWORD PTR [rbp-4]
```
Non-optimizing MSVC just uses IMUL instruction:

Listing 1.260: Non-optimizing MSVC 2013 x64

```
movsx  rdx, eax
; RDX = sign-extended input value
mov     rax, rdx
; RAX = month
sal     rax, 2
; RAX = month<<2 = month*4
add     rax, rdx
; RAX = RAX+RDX = month*4+month = month*5
add     rax, rax
; RAX = RAX*2 = month*5*2 = month*10
add     rax, OFFSET FLAT:month2
; RAX = month*10 + pointer to the table
pop     rbp
ret
```

But one thing is weird here: why add multiplication by zero and adding zero to the final result?

This looks like a compiler code generator quirk, which wasn’t caught by the compiler’s tests (the resulting code works correctly, after all). We intentionally consider such pieces of code so the reader would understand, that sometimes one shouldn’t puzzle over such compiler artifacts.

### 32-bit ARM

Optimizing Keil for Thumb mode uses the multiplication instruction MULS:

Listing 1.261: Optimizing Keil 6/2013 (Thumb mode)

```

MOVS     r1,#0xa

MULS     r0,r1,r0

LDR     r1,|L0.68|

ADD     r0,r0,r1

BX     lr
```

Optimizing Keil for ARM mode uses add and shift operations:

Listing 1.262: Optimizing Keil 6/2013 (ARM mode)

```

LDR     r1,|L0.104|
```
;  R1 = pointer to the table
ADD    r0, r0, r0, LSL #2
;  R0 = R0+R0<<2 = R0+R0*4 = month*5
ADD    r0, r1, r0, LSL #1
;  R0 = R1+R0<<2 = pointer to the table + month*5*2 = pointer to the table + month*10
BX     lr

ARM64

Listing 1.263: Optimizing GCC 4.9 ARM64

;  W0 = month
sxtw   x0, w0
;  X0 = sign-extended input value
adrp   x1, .LANCHOR1
add    x1, x1, :lo12:.LANCHOR1
;  X1 = pointer to the table
add    x0, x0, x0, lsl 2
;  X0 = X0*X0<<2 = X0+X0*4 = X0*5
add    x0, x1, x0, lsl 1
;  X0 = X1+X0<<1 = X1+X0*2 = pointer to the table + X0*10
ret

SXTW is used for sign-extension and promoting input 32-bit value into a 64-bit one and storing it in X0.
ADRP/ADD pair is used for loading the address of the table.
The ADD instructions also has a LSL suffix, which helps with multiplications.

MIPS

Listing 1.264: Optimizing GCC 4.4.5 (IDA)

.globl get_month2
get_month2:
  ;  $a0=month
  sll   $v0, $a0, 3
  ;  $v0 = $a0<<3 = month*8
  sll   $a0, 1
  ;  $a0 = $a0<<1 = month*2
  addu  $a0, $v0
  ;  $a0 = month*2+month*8 = month*10
  ; load address of the table:
  la    $v0, month2
  ; sum up table address and index we calculated and return:
  jr     $ra
  addu  $v0, $a0

month2:   .ascii "January"<0>
  .byte 0, 0
aFebruary: .ascii "February"<0>
  .byte 0
aMarch:    .ascii "March"<0>
  .byte 0, 0, 0, 0

Conclusion

This is a bit old-school technique to store text strings. You may find a lot of it in Oracle RDBMS, for example. It’s hard to say if it’s worth doing on modern computers. Nevertheless, it is a good example of arrays, so it was added to this book.

1.26.8 Conclusion

An array is a pack of values in memory located adjacently. It’s true for any element type, including structures.

Access to a specific array element is just a calculation of its address.

So, a pointer to an array and address of a first element—is the same thing. This is why ptr[0] and *ptr expressions are equivalent in C/C++. It’s interesting to note that Hex-Rays often replaces the first by the second. It does so when it have no idea that it works with pointer to the whole array, and thinks that this is a pointer to single variable.

1.27 Example: a bug in Angband

An ancient rogue-like game from 1990’s had a nice bug:

From: be...@uswest.com (George Bell)
Subject: [Angband] Multiple artifact copies found (bug?)
Date: Fri, 23 Jul 1993 15:55:08 GMT

Up to 2000 ft I found only 4 artifacts, now my house is littered with the suckers (FYI, most I’ve gotten from killing nasties, like Dracoliches and the like). Something really weird is happening now, as I found multiple copies of the same artifact! My half-elf ranger is down at 2400 ft on one level which is particularly nasty. There is a graveyard plus monsters surrounded by permanent rock and 2 or 3 other special monster rooms! I did so much slashing with my favorite weapon, Crisdurian, that I filled several rooms nearly to the brim with treasure (as usual, mostly junk).

Then, when I found a way into the big vault, I noticed some of the treasure had already been identified (in fact it looked strangely familiar!). Then I found *two* Short Swords named Sting (1d6) (+7,+8), and I just ran across a third copy! I have seen multiple copies of Gurthang on this level as well. Is there some limit on the number of items per level which I have exceeded? This sounds reasonable as all multiple copies I have seen come from this level.

I'm playing PC angband. Anybody else had this problem?

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Help! I need a Rod of Restore Life Levels, if there is such a thing. These Graveyards are nasty (Black Reavers and some speed 2 wraith in particular).

(https://groups.google.com/forum/#!original/rec.games.moria/jItmfrdGyL8/8csctQqA7PQJ)

From: Ceri <cm...@andrew.cmu.edu>
Subject: Re: [Angband] Multiple artifact copies found (bug?)
Date: Fri, 23 Jul 1993 23:32:20 -0400

welcome to the mush bug. if there are more than 256 items
on the floor, things start duplicating. learn to harness
this power and you will win shortly :>

--Rick

(https://groups.google.com/forum/#!search/angband$202.4$20bug$20multiplying$20items/rec. games.moria/jItmfrdGyL8/FoQeiccewHAJ)

From: nwe...@soda.berkeley.edu (Nicholas C. Weaver)
Subject: Re: [Angband] Multiple artifact copies found (bug?)
Date: 24 Jul 1993 18:18:05 GMT

In article <74348474...@unix1.andrew.cmu.edu> Ceri <cm...@andrew.cmu.edu> writes:
>welcome to the mush bug. if there are more than 256 items
>on the floor, things start duplicating. learn to harness
>this power and you will win shortly :>
>
>--Rick

Question on this. Is it only the first 256 items which get
duplicated? What about the original items? Etc Etc Etc...

Oh, for those who like to know about bugs, though, the -n option
(start new character) has the following behavior:

(this is in version 2.4.Frog.knows on unix)

If you hit controll-p, you keep your old stats.

YOU loose all record of artifacts founds and named monsters killed.

YOU loose all items you are carrying (they get turned into error in
objid()s ).

You loose your gold.

You KEEP all the stuff in your house.

If you kill something, and then quaff a potion of restore life
levels, you are back up to where you were before in EXPERIENCE POINTS!!

Gaining spells will not work right after this, unless you have a
gain int item (for spellcasters) or gain wis item (for priests/palidans), in
which case after performing the above, then take the item back on and off,
you will be able to learn spells normally again.

This can be exploited, if you are a REAL H0ZER (like me), into
going multiple artifacts early on. Just get to a level where you can
pound wormtongue into the ground, kill him, go up, drop your stuff in your
house, buy a few potions of restore exp and high value spellbooks with your
leftover gold, angband -n yourself back to what you were before, and repeat
the process. Yes, you CAN kill wormtongue multiple times. :)

This also allows the creation of a human rogue with dunedain warrior
starting stats.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Of course, such practices are evil, vile, and disgusting. I take no
liability for the results of spreading this information. Yeah, it's another
bug to go onto the pile.

Nicholas C. Weaver perpetual ensign guppy mwe...@soda.berkeley.edu

It is a tale, told by an idiot, full of sound and fury, .signifying nothing.

Since C evolved out of B, and a C+ is close to a B,
does that mean that C++ is a devolution of the language?

(https://groups.google.com/forum/#!original/rec.games.moria/jItmfrdGyL8/FoQeiccewHAJ)
The whole thread: https://groups.google.com/forum/#!search/angband$202.4$20bug$20multiplying$20items/rec.games.moria/jItmfrdGyL8/FoQeiccewHAJ.
The author of these lines found the version with the bug (2.4 fk) 145, and we can clearly see how global arrays are declared:

/* Number of dungeon objects */
#define MAX_DUNGEON_OBJ 423

int16 sorted_objects[MAX_DUNGEON_OBJ];

/* Identified objects flags */
int8u object_ident[OBJECT_IDENT_SIZE];
t_level[MAX_OBJ_LEVEL+1];
inven_type_t_list[MAX_TALLOC];
inven_type_inventory[INVEN_ARRAY_SIZE];

Perhaps this is a reason. The MAX_DUNGEON_OBJ constant is too small. Perhaps, authors should use linked lists or other data structures, which are unlimited by size. But arrays are simpler to use.

Another example of buffer overflow over globally defined arrays: 3.28 on page 643.

### 1.28 Manipulating specific bit(s)

A lot of functions define their input arguments as flags in bit fields.

Of course, they could be substituted by a set of bool-typed variables, but it is not frugally.

#### 1.28.1 Specific bit checking

**x86**

Win32 API example:

```c
HANDLE fh;

fh=CreateFile ("file", GENERIC_WRITE | GENERIC_READ, FILE_SHARE_READ, NULL, OPEN_ALWAYS,
\, FILE_ATTRIBUTE_NORMAL, NULL);
```

We get (MSVC 2010):

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>push 0</td>
<td>0</td>
</tr>
<tr>
<td>push 128</td>
<td>; 00000000H</td>
</tr>
<tr>
<td>push 4</td>
<td></td>
</tr>
<tr>
<td>push 0</td>
<td></td>
</tr>
<tr>
<td>push 1</td>
<td></td>
</tr>
<tr>
<td>push -1073741824</td>
<td>; c000000H</td>
</tr>
<tr>
<td>push OFFSET $SG78813</td>
<td></td>
</tr>
<tr>
<td>call DWORD PTR __imp__CreateFileA@28</td>
<td></td>
</tr>
<tr>
<td>mov DWORD PTR _fh$[ebp], eax</td>
<td></td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Let’s take a look in WinNT.h:

### Listing 1.266: WinNT.h

```c
#define GENERIC_READ  (0x80000000L)
#define GENERIC_WRITE (0x40000000L)
#define GENERIC_EXECUTE (0x20000000L)
#define GENERIC_ALL   (0x10000000L)
```

Everything is clear, `GENERIC_READ | GENERIC_WRITE = 0x80000000 | 0x40000000 = 0xC0000000`, and that value is used as the second argument for the `CreateFile()` function.

How would `CreateFile()` check these flags?

If we look in `KERNEL32.DLL` in Windows XP SP3 x86, we’ll find this fragment of code in `CreateFileW`:

### Listing 1.267: KERNEL32.DLL (Windows XP SP3 x86)

```c
.text:7C83D429 test byte ptr [ebp+dwDesiredAccess+3], 40h
.text:7C83D42D mov [ebp+var_8], 1
.text:7C83D434 jz short loc_7C83D417
.text:7C83D436 jmp loc_7C810817
```

Here we see the `TEST` instruction, however it doesn’t take the whole second argument, but only the most significant byte (`ebp+dwDesiredAccess+3`) and checks it for flag `0x40` (which implies the `GENERIC_WRITE` flag here).

`TEST` is basically the same instruction as `AND`, but without saving the result (recall the fact `CMP` is merely the same as `SUB`, but without saving the result (1.12.4 on page 86)).

The logic of this code fragment is as follows:

```c
if ((dwDesiredAccess&0x40000000) == 0) goto loc_7C83D417
```

If `AND` instruction leaves this bit, the ZF flag is to be cleared and the JZ conditional jump is not to be triggered. The conditional jump is triggered only if the `0x40000000` bit is absent in `dwDesiredAccess` variable —then the result of `AND` is 0, ZF is to be set and the conditional jump is to be triggered.

Let’s try GCC 4.4.1 and Linux:

```c
#include <stdio.h>
#include <fcntl.h>

void main()
{
    int handle;
    handle=open("file", O_RDWR | O_CREAT);
}
```

We get:

### Listing 1.268: GCC 4.4.1

```c
main proc near
    var_20 = dword ptr -20h
    var_1C = dword ptr -1Ch
    var_4  = dword ptr -4

    push ebp
    mov ebp, esp
    and esp, 0FFFFFFF0h
    sub esp, 20h
    mov [esp+20h+var_1C], 42h
    mov [esp+20h+var_20], offset aFile ; "file"
    call open
    mov [esp+20h+var_4], eax
    leave
    retn
main endp
```

(For statistics collecting purposes) if you’ve read this far, please click [here](msdn.microsoft.com/en-us/library/aa363858(VS.85).aspx). Thanks!
If we take a look in the `open()` function in the `libc.so.6` library, it is only a syscall:

![Listing 1.269: open() (libc.so.6)](image)

So, the bit fields for `open()` are apparently checked somewhere in the Linux kernel.

Of course, it is easy to download both Glibc and the Linux kernel source code, but we are interested in understanding the matter without it.

So, as of Linux 2.6, when the `sys_open` syscall is called, control eventually passes to `do_sys_open`, and from there—to the `do_filp_open()` function (it's located in the kernel source tree in `fs/namei.c`).

N.B. Aside from passing arguments via the stack, there is also a method of passing some of them via registers. This is also called fastcall (6.1.3 on page 734). This works faster since CPU does not need to access the stack in memory to read argument values. GCC has the option `regparm`\(^{147}\), through which it's possible to set the number of arguments that can be passed via registers.

The Linux 2.6 kernel is compiled with `-mregparm=3` option\(^{148}\)\(^{149}\).

What this means to us is that the first 3 arguments are to be passed via registers EAX, EDX and ECX, and the rest via the stack. Of course, if the number of arguments is less than 3, only part of registers set is to be used.

So, let's download Linux Kernel 2.6.31, compile it in Ubuntu: `make vmlinux`, open it in IDA, and find the `do_filp_open()` function. At the beginning, we see (the comments are mine):

![Listing 1.270: do_filp_open() (linux kernel 2.6.31)](image)

GCC saves the values of the first 3 arguments in the local stack. If that wasn’t done, the compiler would not touch these registers, and that would be too tight environment for the compiler’s register allocator.

Let’s find this fragment of code:

![Listing 1.271: do_filp_open() (linux kernel 2.6.31)](image)

\(^{147}\)ohse.de/uwe/articles/gcc-attributes.html#func-regparm

\(^{148}\)kernelnewbies.org/Linux_2_6_20#head-042c62f290834eb1fe0a1942bfbf5bb9a4accbc8f

\(^{149}\)See also arch/x86/include/asm/calling.h file in kernel tree

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
0x40—is what the O_CREAT macro equals to. open_flag gets checked for the presence of the 0x40 bit, and if this bit is 1, the next JNZ instruction is triggered.

**ARM**

The O_CREAT bit is checked differently in Linux kernel 3.8.0.

Listing 1.272: linux kernel 3.8.0

```c
struct file *do_filp_open(int dfd, struct filename *pathname,
    const struct open_flags *op)
{
    ...  filp = path_openat(dfd, pathname, &nd, op, flags | LOOKUP_RCU);
    ...
}
static struct file *path_openat(int dfd, struct filename *pathname,
    struct nameidata *nd, const struct open_flags *op, int flags)
{
    ...  error = do_last(nd, &path, file, op, &opened, pathname);
    ...
}
static int do_last(struct nameidata *nd, struct path *path,
    struct file *file, const struct open_flags *op,
    int *opened, struct filename *name)
{
    ...  if (!((open_flag & O_CREAT)) {
        ...   error = lookup_fast(nd, path, &inode);
        ...
    } else {
        ...   error = complete_walk(nd);
        ...
}
}
```

Here is how the kernel compiled for ARM mode looks in **IDA**:

Listing 1.273: do_last() from vmlinux (IDA)

```
... .text:C0169EA8  MOV  R9, R3 ; R3 - (4th argument) open_flag
... .text:C0169ED4  LDR  R6, [R9] ; R6 - open_flag
... .text:C0169F68  TST  R6, #0x40 ; jumptable C0169F00 default case
    .text:C0169F6C  BNE  loc_C016A128
    .text:C0169F70  LDR  R2, [R4,#0x10]
    .text:C0169F74  ADD  R12, R4, #8
    .text:C0169F78  LDR  R3, [R4,#0xC]
    .text:C0169F7C  MOV  R0, R4
    .text:C0169F80  STR  R12, [R11,#var_50]
    .text:C0169F84  LDRB  R3, [R2,R3]
    .text:C0169F88  MOV  R2, R8
    .text:C0169F8C  CMP  R3, #0
    .text:C0169F90  ORRNE  R1, R1, #3
    .text:C0169F94  STRNE  R1, [R4,#0x24]
    .text:C0169F98  ANDS  R3, R6, #0x200000
    .text:C0169F9C  MOV  R1, R12
    .text:C0169FA0  LDRNE  R3, [R4,#0x24]
    .text:C0169FA4  ANDNE  R3, R3, #1
    .text:C0169FA8  EORNE  R3, R3, #1
    .text:C0169FAC  STR  R3, [R11,#var_54]
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
TST is analogous to the TEST instruction in x86. We can “spot” visually this code fragment by the fact the `lookup_fast()` is to be executed in one case and `complete_walk()` in the other. This corresponds to the source code of the `do_last()` function. The `_O_CREAT` macro equals to 0x40 here too.

### 1.28.2 Setting and clearing specific bits

For example:

```c
#include <stdio.h>

#define IS_SET(flag, bit) ((flag) & (bit))
#define SET_BIT(var, bit) ((var) |= (bit))
#define REMOVE_BIT(var, bit) ((var) &= ~(bit))

int f(int a)
{
    int rt=a;
    SET_BIT (rt, 0x4000);
    REMOVE_BIT (rt, 0x200);
    return rt;
}

int main()
{
    f(0x12340678);
}
```

### x86

**Non-optimizing MSVC**

We get (MSVC 2010):

```assembly
          _rt$ = -4 ; size = 4
          _a$ = 8 ; size = 4
_f PROC
    push ebp
    mov ebp, esp
    push ecx
    mov eax, DWORD PTR _a$[ebp]
    mov DWORD PTR _rt$[ebp], eax
    mov ecx, DWORD PTR _rt$[ebp]
    or ecx, 16384 ; 00004000H
    mov DWORD PTR _rt$[ebp], ecx
    mov edx, DWORD PTR _rt$[ebp]
    and edx, -513 ; ffffffH
    mov DWORD PTR _rt$[ebp], edx
    mov eax, DWORD PTR _rt$[ebp]
    mov esp, edx
    mov ebx, eax
    leave
    ret 0
_f ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
The OR instruction sets one bit into a register while ignoring other 1 bits.

AND resets one bit. It can be said that AND just copies all bits except one. Indeed, in the second AND operand only the bits that need to be saved are set, just the one do not want to copy is not (which is 0 in the bitmask). It is the easier way to memorize the logic.
OllyDbg

Let’s try this example in OllyDbg.

First, let’s see the binary form of the constants we are going to use:
0x200 (0b00000000000000000000000000000000) (i.e., the 10th bit (counting from 1st)).
Inverted 0x200 is 0xFFFFFDFF (0b111111111111111101111111).
0x4000 (0b00000000000000000000000000000000) (i.e., the 15th bit).
The input value is: 0x12340678 (0b10010001101000000011001111000). We see how it’s loaded:

Figure 1.95: OllyDbg: value is loaded into ECX

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
OR got executed:

Figure 1.96: OllyDbg: OR executed

15th bit is set: 0x1234678 (0b1001000110100100011001111000).
The value is reloaded again (because the compiler is not in optimizing mode):

![CPU - main thread, module set_reset](image)

**Figure 1.97:** OllyDbg: value has been reloaded into EDX

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
AND got executed:

The 10th bit has been cleared (or, in other words, all bits were left except the 10th) and the final value now is 0x1234478 (0b1001000110100010001111000).

**Optimizing MSVC**

If we compile it in MSVC with optimization turned on (/Ox), the code is even shorter:

```
Listing 1.275: Optimizing MSVC

_a$ = 8 ; size = 4
_f PROC
  mov eax, DWORD PTR _a$[esp-4]
  and eax, -513 ; ffffffffH
  or eax, 16384 ; 00004000H
  ret 0
_f ENDP
```

**Non-optimizing GCC**

Let's try GCC 4.4.1 without optimization:

```
Listing 1.276: Non-optimizing GCC

public f
_f proc near
var 4 = dword ptr -4
arg 0 = dword ptr 8
push ebp
mov ebp, esp
sub esp, 10h
mov eax, [ebp+arg_0]
mov [ebp+var_4], eax
or [ebp+var_4], 4000h
and [ebp+var_4], 0FFFFFFF
mov eax, [ebp+var_4]
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
There is a redundant code present, however, it is shorter than the MSVC version without optimization. Now let's try GCC with optimization turned on -O3:

**Optimizing GCC**

Now let’s try GCC with optimization turned on -O3:

Listing 1.277: Optimizing GCC

```plaintext
public f
f proc near
arg_0 = dword ptr 8
    push ebp
    mov ebp, esp
    mov eax, [ebp+arg_0]
    pop ebp
    or ah, 40h
    and ah, 0FDh
retn
f endp
```

That’s shorter. It is worth noting the compiler works with the EAX register part via the AH register—that is the EAX register part from the 8th to the 15th bits included.

### Byte number:

<table>
<thead>
<tr>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>EAX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>AX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>AH</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

N.B. The 16-bit CPU 8086 accumulator was named AX and consisted of two 8-bit halves—AL (lower byte) and AH (higher byte). In 80386 almost all registers were extended to 32-bit, the accumulator was named EAX, but for the sake of compatibility, its older parts may be still accessed as AX/AH/AL.

Since all x86 CPUs are successors of the 16-bit 8086 CPU, these older 16-bit opcodes are shorter than the newer 32-bit ones. That’s why the or ah, 40h instruction occupies only 3 bytes. It would be more logical way to emit here or eax, 04000h but that is 5 bytes, or even 6 (in case the register in the first operand is not EAX).

**Optimizing GCC and regparm**

It would be even shorter if to turn on the -O3 optimization flag and also set regparm=3.

Listing 1.278: Optimizing GCC

```plaintext
public f
f proc near
push ebp
or ah, 40h
mov ebp, esp
and ah, 0FDh
pop ebp
retn
f endp
```

Indeed, the first argument is already loaded in EAX, so it is possible to work with it in-place. It is worth noting that both the function prologue (push ebp / mov ebp,esp) and epilogue (pop ebp) can easily be omitted here, but GCC probably is not good enough to do such code size optimizations. However, such short functions are better to be *inlined functions* (3.12 on page 514).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
### ARM + Optimizing Keil 6/2013 (ARM mode)

Listing 1.279: Optimizing Keil 6/2013 (ARM mode)

```
02 0C C0 E3  BIC    R0, R0, #0x200
01 09 80 E3  ORR    R0, R0, #0x4000
1E FF 2F E1  BX     LR
```

BIC (*Bitwise bit Clear*) is an instruction for clearing specific bits. This is just like the AND instruction, but with inverted operand. I.e., it’s analogous to a NOT + AND instruction pair.

ORR is “logical or”, analogous to OR in x86.

So far it’s easy.

### ARM + Optimizing Keil 6/2013 (Thumb mode)

Listing 1.280: Optimizing Keil 6/2013 (Thumb mode)

```
01 21 89 03  MOVS   R1, 0x4000
08 43  ORRS   R0, R1
49 11  ASRS   R1, R1, #5  ; generate 0x200 and place to R1
88 43  BICS   R0, R1
70 47  BX     LR
```

Seems like Keil decided that the code in Thumb mode, making 0x200 from 0x4000, is more compact than the code for writing 0x200 to an arbitrary register.

So that is why, with the help of ASRS (arithmetic shift right), this value is calculated as $0x4000 \gg 5$.

### ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 1.281: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```
42 0C C0 E3  BIC    R0, R0, #0x4200
01 09 80 E3  ORR    R0, R0, #0x4000
1E FF 2F E1  BX     LR
```

The code that was generated by LLVM, in source code form could be something like this:

```c
REMOVE_BIT (rt, 0x4200);
SET_BIT (rt, 0x4000);
```

And it does exactly what we need. But why 0x4200? Perhaps that an artifact from LLVM’s optimizer.\(^{150}\) Probably a compiler’s optimizer error, but the generated code works correctly anyway.

You can read more about compiler anomalies here (11.4 on page 973).

Optimizing Xcode 4.6.3 (LLVM) for Thumb mode generates the same code.

### ARM: more about the BIC instruction

Let’s rework the example slightly:

```c
int f(int a)
{
    int rt=a;
    REMOVE_BIT (rt, 0x1234);
    return rt;
}
```

Then the optimizing Keil 5.03 in ARM mode does:

\(^{150}\)It was LLVM build 2410.2.00 bundled with Apple Xcode 4.6.3

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
There are two BIC instructions, i.e., bits $0x1234$ are cleared in two passes.
This is because it’s not possible to encode $0x1234$ in a BIC instruction, but it’s possible to encode $0x1000$ and $0x234$.

**ARM64: Optimizing GCC (Linaro) 4.9**

Optimizing GCC compiling for ARM64 can use the AND instruction instead of BIC:

```assembly
Listing 1.282: Optimizing GCC (Linaro) 4.9

f:
    and  w0, w0, -513 ; 0xFFFFFFFFFFFFDFF
    orr  w0, w0, 16384 ; 0x4000
    ret
```

**ARM64: Non-optimizing GCC (Linaro) 4.9**

Non-optimizing GCC generates more redundant code, but works just like optimized:

```assembly
Listing 1.283: Non-optimizing GCC (Linaro) 4.9

f:
    sub  sp, sp, #32
    str  w0, [sp,12]
    ldr  w0, [sp,12]
    str  w0, [sp,28]
    ldr  w0, [sp,28]
    orr  w0, w0, 16384 ; 0x4000
    str  w0, [sp,28]
    ldr  w0, [sp,28]
    and  w0, w0, -513 ; 0xFFFFFFFFFFFFDFF
    str  w0, [sp,28]
    ldr  w0, [sp,28]
    add  sp, sp, 32
    ret
```

**MIPS**

```assembly
Listing 1.284: Optimizing GCC 4.4.5 (IDA)

f:
    ; $a0=a
    ori  $a0, 0x4000
    ; $a0=a|0x4000
    li   $v0, 0xFFFFFFFFDFF
    jr   $ra
    and  $v0, $a0, $v0
    ; at finish: $v0 = $a0 & $v0 = a|0x4000 & 0xFFFFFFFFDFF
```

ORI is, of course, the OR operation. “I” in the instruction name means that the value is embedded in the machine code.

But after that we have AND. There is no way to use ANDI because it’s not possible to embed the 0xFFFFFFFFDFF number in a single instruction, so the compiler has to load 0xFFFFFFFFDFF into register $V0 first and then generates AND which takes all its values from registers.
### 1.28.3 Shifts

Bit shifts in C/C++ are implemented using « and » operators. The x86 ISA has the SHL (SHift Left) and SHR (SHift Right) instructions for this. Shift instructions are often used in division and multiplications by powers of two: \(2^n\) (e.g., 1, 2, 4, 8, etc.): [1.24.1 on page 215, 1.24.2 on page 219].

Shifting operations are also so important because they are often used for specific bit isolation or for constructing a value of several scattered bits.

### 1.28.4 Setting and clearing specific bits: FPU example

Here is how bits are located in the float type in IEEE 754 form:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>23</th>
<th>22</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td>mantissa or fraction</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The sign of number is in the MSB\(^{151}\). Will it be possible to change the sign of a floating point number without any FPU instructions?

```c
#include <stdio.h>

float my_abs (float i)
{
    unsigned int tmp=(*{(unsigned int*)&i} & 0x7FFFFFFF);
    return *(float*)&tmp;
};

float set_sign (float i)
{
    unsigned int tmp=(*{(unsigned int*)&i} | 0x80000000);
    return *(float*)&tmp;
};

float negate (float i)
{
    unsigned int tmp=(*{(unsigned int*)&i} ^ 0x80000000);
    return *(float*)&tmp;
};

int main()
{
    printf("my_abs():\n");
    printf("%f\n", my_abs (123.456));
    printf("%f\n", my_abs (-456.123));
    printf("set_sign():\n");
    printf("%f\n", set_sign (123.456));
    printf("%f\n", set_sign (-456.123));
    printf("negate():\n");
    printf("%f\n", negate (123.456));
    printf("%f\n", negate (-456.123));
};
```

We need this trickery in C/C++ to copy to/from float value without actual conversion. So there are three functions: my_abs() resets MSB; set_sign() sets MSB and negate() flips it.
XOR can be used to flip a bit: [2.6 on page 466].

### x86

The code is pretty straightforward:

\(^{151}\)Most Significant Bit

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.285: Optimizing MSVC 2012

```assembly
_tmp$ = 8
_i$ = 8
_my_abs PROC
  and DWORD PTR _i$[esp-4], 2147483647 ; 7fffffffH
  fld DWORD PTR _tmp$[esp-4]
  ret 0
_my_abs ENDP

tmp$ = 8
_i$ = 8
_set_sign PROC
  or DWORD PTR _i$[esp-4], -2147483648 ; 80000000H
  fld DWORD PTR _tmp$[esp-4]
  ret 0
_set_sign ENDP

tmp$ = 8
_i$ = 8
_negate PROC
  xor DWORD PTR _i$[esp-4], -2147483648 ; 80000000H
  fld DWORD PTR _tmp$[esp-4]
  ret 0
_negate ENDP
```

An input value of type `float` is taken from the stack, but treated as an integer value.

AND and OR reset and set the desired bit. XOR flips it.

Finally, the modified value is loaded into ST0, because floating-point numbers are returned in this register.

Now let’s try optimizing MSVC 2012 for x64:

Listing 1.286: Optimizing MSVC 2012 x64

```assembly
_tmp$ = 8
_i$ = 8
my_abs PROC
  movss DWORD PTR [rsp+8], xmm0
  mov eax, DWORD PTR i$[rsp]
  btr eax, 31
  mov DWORD PTR tmp$[rsp], eax
  movss xmm0, DWORD PTR tmp$[rsp]
  ret 0
my_abs ENDP
_TEXT ENDS

tmp$ = 8
_i$ = 8
_set_sign PROC
  movss DWORD PTR [rsp+8], xmm0
  mov eax, DWORD PTR i$[rsp]
  bts eax, 31
  mov DWORD PTR tmp$[rsp], eax
  movss xmm0, DWORD PTR tmp$[rsp]
  ret 0
_set_sign ENDP

tmp$ = 8
_i$ = 8
_negate PROC
  movss DWORD PTR [rsp+8], xmm0
  mov eax, DWORD PTR i$[rsp]
  btc eax, 31
  mov DWORD PTR tmp$[rsp], eax
  movss xmm0, DWORD PTR tmp$[rsp]
  ret 0
_negate ENDP
```

The input value is passed in `XMM0`, then it is copied into the local stack and then we see some instructions that are new to us: BTR, BTS, BTC.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
These instructions are used for resetting (BTR), setting (BTS) and inverting (or complementing: BTC) specific bits. The 31st bit is MSB, counting from 0.

Finally, the result is copied into XMM0, because floating point values are returned through XMM0 in Win64 environment.

**MIPS**

GCC 4.4.5 for MIPS does mostly the same:

![Listing 1.287: Optimizing GCC 4.4.5 (IDA)](image)

One single LUI instruction is used to load 0x80000000 into a register, because LUI is clearing the low 16 bits and these are zeros in the constant, so one LUI without subsequent ORI is enough.

**ARM**

Optimizing Keil 6/2013 (ARM mode)

![Listing 1.288: Optimizing Keil 6/2013 (ARM mode)](image)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
So far so good.

ARM has the BIC instruction, which explicitly clears specific bit(s). EOR is the ARM instruction name for XOR (“Exclusive OR”).

Optimizing Keil 6/2013 (Thumb mode)

The code of my_abs is weird and it effectively works like this expression: \((i\ll 1)\gg 1\). This statement looks meaningless. But nevertheless, when \(input\ll 1\) is executed, the MSB (sign bit) is just dropped. When the subsequent \(result\gg 1\) statement is executed, all bits are now in their own places, but MSB is zero, because all “new” bits appearing from the shift operations are always zeros. That is how the LSLS/LSRS instruction pair clears MSB.

Optimizing GCC 4.6.3 (Raspberry Pi, ARM mode)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s run Raspberry Pi Linux in QEMU and it emulates an ARM FPU, so S-registers are used here for floating point numbers instead of R-registers.

The FMRS instruction copies data from GPR to the FPU and back.

my_abs() and set_sign() looks as expected, but negate()? Why is there ADD instead of XOR?

It’s hard to believe, but the instruction ADD register, 0x80000000 works just like XOR register, 0x80000000. First of all, what’s our goal? The goal is to flip the MSB, so let’s forget about the XOR operation. From school-level mathematics we may recall that adding values like 1000 to other values never affects the last 3 digits. For example: 1234567 + 10000 = 1244567 (last 4 digits are never affected).

But here we operate in binary base and 0x80000000 is 0b10000000000000000000000000000000, i.e., only the highest bit is set.

Adding 0x80000000 to any value never affects the lowest 31 bits, but affects only the MSB. Adding 1 to 0 is resulting in 1.

Adding 1 to 1 is resulting in 0b10 in binary form, but the 32th bit (counting from zero) gets dropped, because our registers are 32 bit wide, so the result is 0. That’s why XOR can be replaced by ADD here.

It’s hard to say why GCC decided to do this, but it works correctly.

1.28.5 Counting bits set to 1

Here is a simple example of a function that calculates the number of bits set in the input value.

This operation is also called “population count”\(^{152}\).

```c
#include <stdio.h>

#define IS_SET(flag, bit) ((flag) & (bit))

int f(unsigned int a)
{
    int i;
    int rt=0;

    for (i=0; i<32; i++)
        if (IS_SET (a, 1<<i))
            rt++;

    return rt;
}
```

\(^{152}\)modern x86 CPUs (supporting SSE4) even have a POPCNT instruction for it
In this loop, the iteration count value $i$ is counting from 0 to 31, so the $1 \ll i$ statement is counting from 1 to $0x80000000$. Describing this operation in natural language, we would say *shift 1 by n bits left*. In other words, $1 \ll i$ statement consequently produces all possible bit positions in a 32-bit number. The freed bit at right is always cleared.

Here is a table of all possible $1 \ll i$ for $i = 0 \ldots 31$:

<table>
<thead>
<tr>
<th>C/C++ expression</th>
<th>Power of two</th>
<th>Decimal form</th>
<th>Hexadecimal form</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1 \ll 0$</td>
<td>$2^0$</td>

<td>0x800000000</td>
</tr>
</tbody>
</table>

These constant numbers (bit masks) very often appear in code and a practicing reverse engineer must be able to spot them quickly.

Decimal numbers below 65536 and hexadecimal ones are very easy to memorize. While decimal numbers above 65536 are, probably, not worth memorizing.

These constants are very often used for mapping flags to specific bits. For example, here is excerpt from ssl_private.h from Apache 2.4.6 source code:

```c
#define SSL_OPT_NONE (0)
#define SSL_OPT_RELSET (1<<0)
#define SSL_OPT_STDENVVARS (1<<1)
#define SSL_OPT_EXPORTCERTDATA (1<<3)
#define SSL_OPT_FAKEBASICAUTH (1<<4)
#define SSL_OPT_STRICTREQUIRE (1<<5)
#define SSL_OPT_OPTRENEGOTIATE (1<<6)
#define SSL_OPT_LEGACYDNFORMAT (1<<7)
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!"
Let's get back to our example.

The IS_SET macro checks bit presence in $a$.
The IS_SET macro is in fact the logical AND operation (AND) and it returns 0 if the specific bit is absent there, or the bit mask, if the bit is present. The if() operator in C/C++ triggers if the expression in it is not zero, it might be even 123456, that is why it always works correctly.

x86

MSVC

Let's compile (MSVC 2010):

```
Listing 1.291: MSVC 2010

    _rt$ = -8    ; size = 4
    _i$  = -4    ; size = 4
    _a$  = 8     ; size = 4

_f PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 8
    mov     DWORD PTR _rt$[ebp], 0
    mov     DWORD PTR _i$[ebp], 0
    jmp     SHORT $LN4@f
$LN3@f:
    mov     eax, DWORD PTR _i$[ebp]           ; increment of i
    add     eax, 1
    mov     DWORD PTR _i$[ebp], eax
$LN4@f:
    cmp     DWORD PTR _i$[ebp], 32           ; 00000020H
    jge     SHORT $LN2@f
    mov     edx, 1
    mov     ecx, DWORD PTR _i$[ebp]
    shl     edx, cl                            ; EDX=EDX<<CL
    and     edx, DWORD PTR _a$[ebp]
    je      SHORT $LN1@f                      ; result of AND instruction was 0?
                                        ; then skip next instructions
    mov     eax, DWORD PTR _rt$[ebp]           ; no, not zero
    add     eax, 1
                                        ; increment rt
$LN1@f:
    jmp     SHORT $LN3@f
$LN2@f:
    mov     eax, DWORD PTR _rt$[ebp]
    mov     esp, ebp
    pop     ebp
    ret    0
_f    ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let's load this example into OllyDbg. Let the input value be 0x12345678.

For $i = 1$, we see how $i$ is loaded into ECX:

![OllyDbg](image)

Figure 1.99: OllyDbg: $i = 1$, $i$ is loaded into ECX

EDX is 1. SHL is to be executed now.
SHL has been executed:

**Figure 1.100: OllyDbg:** $i = 1$, EDX $= 1 \ll 1 = 2$

EDX contain $1 \ll 1$ (or 2). This is a bit mask.
AND sets ZF to 1, which implies that the input value (0x12345678) ANDed with 2 results in 0:

So, there is no corresponding bit in the input value. The piece of code, which **increments** the counter is not to be executed: the JZ instruction **bypassing** it.
Let's trace a bit further and $i$ is now 4. SHL is to be executed now:

![CPU - main thread, module shifts](image)

---

Figure 1.102: OllyDbg: $i = 4$, $i$ is loaded into ECX

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Figure 1.103: OllyDbg: $i = 4$, $EDX = 1 \ll 4 = 0x10$

This is another bit mask.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
AND is executed:

Figure 1.104: OllyDbg: \(i = 4\), is there that bit in the input value? Yes. (ZF = 0)

ZF is 0 because this bit is present in the input value. Indeed, 0x12345678 & 0x10 = 0x10.

This bit counts: the jump is not triggering and the bit counter incrementing.

The function returns 13. This is total number of bits set in 0x12345678.

GCC

Let's compile it in GCC 4.4.1:

```
Listing 1.292: GCC 4.4.1

public f
f proc near
rt = dword ptr -0Ch
i = dword ptr -8
arg_0 = dword ptr 8

push ebp
mov ebp, esp
push ebx
sub esp, 10h
mov [ebp+rt], 0
mov [ebp+i], 0
jmp short loc_80483EF

loc_80483D0:
    mov eax, [ebp+i]
    mov edx, 1
    mov ebx, edx
    mov ecx, eax
    shl ebx, cl
    mov eax, ebx
    and eax, [ebp+arg_0]
    test eax, eax
    jz short loc_80483EB
    add [ebp+rt], 1
loc_80483EB:
    add [ebp+i], 1
loc_80483EF:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
#include <stdio.h>
#include <stdint.h>

#define IS_SET(flag, bit) ((flag) & (bit))

int f(uint64_t a)
{
    uint64_t i;
    int rt=0;

    for (i=0; i<64; i++)
        if (IS_SET (a, 1ULL<<i))
            rt++;

    return rt;
}
```

### Non-optimizing GCC 4.8.2

So far so easy.

```
f:
    push rbp
    mov rbp, rsp
    mov QWORD PTR [rbp-24], rdi ; a
    mov DWORD PTR [rbp-12], 0 ; rt=0
    mov QWORD PTR [rbp-8], 0 ; i=0
    jmp .L2

.L4:
    mov rax, QWORD PTR [rbp-8]
    mov rdx, QWORD PTR [rbp-24]
    ; RAX = i, RDX = a
    mov ecx, eax
    ; ECX = i
    shr rdx, cl
    ; RDX = RDX>>CL = a>>i
    mov rax, rdx
    ; RAX = RDX = a>>i
    and eax, 1
    ; EAX = EAX&1 = (a>>i)&1
    test rax, rax
    ; the last bit is zero?
    ; skip the next ADD instruction, if it was so.
    je .L3

.L3:
    add DWORD PTR [rbp-12], 1 ; rt++

.L2:
    cmp QWORD PTR [rbp-8], 63 ; i<63?
    jbe .L4 ; jump to the loop body begin, if so
    mov eax, DWORD PTR [rbp-12] ; return rt
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Optimizing GCC 4.8.2

Listing 1.294: Optimizing GCC 4.8.2

```
1 f:
2    xor eax, eax ; rt variable will be in EAX register
3    xor ecx, ecx ; i variable will be in ECX register
4 .L3:
5    mov rsi, rdi ; load input value
6    lea edx, [rax+1] ; EDX=EAX+1
7    ; EDX here is a new version of rt, which will be written into rt variable, if the last bit is 1
8    shr rsi, cl ; RSI=RSI>>CL
9    and esi, 1 ; ESI=ESI&1
10   ; the last bit is 1? If so, write new version of rt into EAX
11   cmovne eax, edx
12   add rcx, 1 ; RCX++
13   cmp rcx, 64
14   jne .L3
15   rep ret ; AKA fatret
```

This code is terser, but has a quirk.

In all examples that we see so far, we were incrementing the “rt” value after comparing a specific bit, but the code here increments “rt” before (line 6), writing the new value into register EDX. Thus, if the last bit is 1, the CMOVNE instruction (which is a synonym for CMOVNZ) commits the new value of “rt” by moving EDX (“proposed rt value”) into EAX (“current rt” to be returned at the end).

Hence, the incrementing is performed at each step of loop, i.e., 64 times, without any relation to the input value.

The advantage of this code is that it contain only one conditional jump (at the end of the loop) instead of two jumps (skipping the “rt” value increment and at the end of loop). And that might work faster on the modern CPUs with branch predictors: 2.10.1 on page 471.

The last instruction is REP RET (opcode F3 C3) which is also called FATRET by MSVC. This is somewhat optimized version of RET, which is recommended by AMD to be placed at the end of function, if RET goes right after conditional jump: [Software Optimization Guide for AMD Family 16h Processors, (2013)p.15]

Optimizing MSVC 2010

Listing 1.295: Optimizing MSVC 2010

```
a$ = 8
f PROC
    ; RCX = input value
    xor eax, eax
    mov edx, 1
    lea r8d, QWORD PTR [rax+64]
    ; R8D=64
    npad 5
$sL4@f:
    test rdx, rcx
    ; there are no such bit in input value?
    ; skip the next INC instruction then.
    je SHORT $LN3@f
    inc eax ; rt++
$sL3@f:
    rol rdx, 1 ; RDX=RDX<<1
```

153 Conditional MOVE if Not Equal
154 Conditional MOVE if Not Zero
155 More information on it: http://go.yurichev.com/17328

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here the ROL instruction is used instead of SHL, which is in fact “rotate left” instead of “shift left”, but in this example it works just as SHL.

You can read more about the rotate instruction here: .1.6 on page 1007.

R8 here is counting from 64 to 0. It’s just like an inverted i.

Here is a table of some registers during the execution:

<table>
<thead>
<tr>
<th>RDX</th>
<th>R8</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000000000000001</td>
<td>64</td>
</tr>
<tr>
<td>0x0000000000000002</td>
<td>63</td>
</tr>
<tr>
<td>0x0000000000000004</td>
<td>62</td>
</tr>
<tr>
<td>0x0000000000000008</td>
<td>61</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>0x4000000000000000</td>
<td>2</td>
</tr>
<tr>
<td>0x8000000000000000</td>
<td>1</td>
</tr>
</tbody>
</table>

At the end we see the FATRET instruction, which was explained here: 1.28.5 on the previous page.

**Optimizing MSVC 2012**

Listing 1.296: Optimizing MSVC 2012

```
a$ = 8
f PROC
; RCX = input value
xor eax, eax
mov edx, 1
lea r8d, QWORD PTR [rax+32]
; EDX = 1, R8D = 32
npad 5
$LL4@f:
; pass 1 ------------------------------
test rdx, rcx
je SHORT $LN3@f
inc eax ; rt++
$LN3@f:
rol rdx, 1 ; RDX=RDX<<1
; pass 2 ------------------------------
test rdx, rcx
je SHORT $LN11@f
inc eax ; rt++
$LN11@f:
rol rdx, 1 ; RDX=RDX<<1
; ------------------------------
dec r8 ; R8--
jne SHORT $LL4@f
fatret 0
f ENDP
```

Optimizing MSVC 2012 does almost the same job as optimizing MSVC 2010, but somehow, it generates two identical loop bodies and the loop count is now 32 instead of 64.

To be honest, it’s not possible to say why. Some optimization trick? Maybe it’s better for the loop body to be slightly longer?

Anyway, such code is relevant here to show that sometimes the compiler output may be really weird and illogical, but perfectly working.
ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 1.297: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```
loc_2E54

TST   R1, R2,LSL R3 ; set flags according to R1 & (R2<<R3)
ADD   R3, R3, #1 ; R3++
ADDNE R0, R0, #1 ; if ZF flag is cleared by TST, then R0++
CMP   R3, #32
BNE   loc_2E54
BX    LR
```

TST is the same thing as TEST in x86.

As was noted before (3.10.3 on page 506), there are no separate shifting instructions in ARM mode. However, there are modifiers LSL (Logical Shift Left), LSR (Logical Shift Right), ASR (Arithmetic Shift Right), ROR (Rotate Right) and RRX (Rotate Right with Extend), which may be added to such instructions as MOV, TST, CMP, ADD, SUB, RSB.

These modifiers define how to shift the second operand and by how many bits.

Thus the “TST R1, R2,LSL R3” instruction works here as $R1 \land (R2 \ll R3)$.

ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

Almost the same, but here are two LSL.W/TST instructions are used instead of a single TST, because in Thumb mode it is not possible to define LSL modifier directly in TST.

```
loc_2F7A

LSL.W R2, R9, R3
TST   R2, R1
ADD  W R3, R3, #1
IT   NE
ADDNE R0, #1
CMP  R3, #32
BNE  loc_2F7A
BX   LR
```

ARM64 + Optimizing GCC 4.9

Let’s take the 64-bit example which has been already used: 1.28.5 on page 333.

Listing 1.298: Optimizing GCC (Linaro) 4.8

```
f:
mov  w2, 0 ; rt=0
mov  x5, 1
mov  w1, w2

.L2:
    lsl x4, x5, x1 ; w4 = w5<<w1 = 1<<i
    add w3, w2, 1 ; new rt=rt+1
    tst x4, x0 ; (1<<i) & a
    add w1, w1, 1 ; i++
    ; result of TST was non-zero?
    ; then w2=w3 or rt=new rt.
    ; otherwise: w2=w2 or rt=rt (idle operation)
    csel w2, w3, w2, ne
    cmp w1, 64 ; i<64?
```

158These instructions are also called “data processing instructions”

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The result is very similar to what GCC generates for x64: 1.294 on page 334.
The CSEL instruction is “Conditional SELect”. It just chooses one variable of two depending on the flags set by TST and copies the value into W2, which holds the “rt” variable.

**ARM64 + Non-optimizing GCC 4.9**

And again, we’ll work on the 64-bit example which was already used: 1.28.5 on page 333. The code is more verbose, as usual.

Listing 1.299: Non-optimizing GCC (Linaro) 4.8

```assembly
f:  
    sub    sp, sp, #32          ; store "a" value to Register Save Area
    str    x0, [sp,8]           
    str    wzr, [sp,24]         ; rt=0
    str    wzr, [sp,28]         ; i=0
    b      .L2
    .L4:  
    ldr    w0, [sp,28]          
    mov    x1, 1                
    lsl    x0, x1, x0           ; X0 = X1<<X0 = 1<<i
    mov    x1, x0
    ; X1 = 1<<i
    ldr    x0, [sp,8]           
    ; X0 = a
    and    x0, x1, x0
    ; X0 contain zero? then jump to .L3, skipping "rt" increment
    cmp    x0, xzr
    beq    .L3
    ; rt++
    ldr    w0, [sp,24]
    add    w0, w0, 1
    str    w0, [sp,24]
    .L3:  
    ; i++
    ldr    w0, [sp,28]
    add    w0, w0, 1
    str    w0, [sp,28]
    .L2:  
    ; i=63? then jump to .L4
    cmp    w0, [sp,28]
    ble    .L4
    ; return rt
    ldr    w0, [sp,24]
    add    sp, sp, 32
    ret
```

**MIPS**

**Non-optimizing GCC**

Listing 1.300: Non-optimizing GCC 4.4.5 (IDA)

```assembly
f:  
    ; IDA is not aware of variable names, we gave them manually:
    rt       = -0x10
    i        = -0xC
    var_4    = -4
    a        = 0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
That is verbose: all local variables are located in the local stack and reloaded each time they’re needed.

The SLLV instruction is “Shift Word Left Logical Variable”, it differs from SLL only in that the shift amount is encoded in the SLL instruction (and is fixed, as a consequence), but SLLV takes shift amount from a register.

Optimizing GCC

That is terser. There are two shift instructions instead of one. Why?

It’s possible to replace the first SLLV instruction with an unconditional branch instruction that jumps right to the second SLLV. But this is another branching instruction in the function, and it’s always favorable to get rid of them: 2.10.1 on page 471.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.301: Optimizing GCC 4.4.5 (IDA)

```assembly
f:
; $a0 = a
; rt variable will reside in $v0:
    move $v0, $zero
; i variable will reside in $v1:
    move $v1, $zero
    li $t0, 1
    li $a3, 32
    sllv $a1, $t0, $v1
; $a1 = $t0<<$v1 = 1<<i
loc_14:
    and $a1, $a0
; $a1 = a&(1<<i)
    increment i:
    addiu $v1, 1
    jump to loc_28 if a&(1<<i)==0 and increment rt:
    beqz $a1, loc_28
        addiu $a2, $v0, 1
    ; if BEQZ was not triggered, save updated rt into $v0:
        move $v0, $a2
loc_28:
; if i!=32, jump to loc_14 and also prepare next shifted value:
    bne $v1, $a3, loc_14
    sllv $a1, $t0, $v1
; return
    jr $ra
or $at, $zero ; branch delay slot, NOP
```

1.28.6 Conclusion

Analogous to the C/C++ shifting operators `≪` and `≫`, the shift instructions in x86 are SHR/SHL (for unsigned values) and SAR/SHL (for signed values).

The shift instructions in ARM are LSR/LSL (for unsigned values) and ASR/LSL (for signed values).

It’s also possible to add shift suffix to some instructions (which are called “data processing instructions”).

### Check for specific bit (known at compile stage)

Test if the 0b1000000 bit (0x40) is present in the register’s value:

Listing 1.302: C/C++

```c
if (input & 0x40)
    ...;
```

Listing 1.303: x86

```
TEST REG, 40h
JNZ is_set
; bit is not set
```

Listing 1.304: x86

```
TEST REG, 40h
JZ is_cleared
; bit is set
```

Listing 1.305: ARM (ARM mode)

```
TST REG, #0x40
BNE is_set
; bit is not set
```

Sometimes, AND is used instead of TEST, but the flags that are set are the same.

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Check for specific bit (specified at runtime)

This is usually done by this C/C++ code snippet (shift value by $n$ bits right, then cut off lowest bit):

Listing 1.306: C/C++

```c
if ((value>>n)&1)
....
```

This is usually implemented in x86 code as:

Listing 1.307: x86

```
; REG=input_value
; CL=n
SHR REG, CL
AND REG, 1
```

Or (shift 1 bit $n$ times left, isolate this bit in input value and check if it’s not zero):

Listing 1.308: C/C++

```c
if (value & (1<<n))
....
```

This is usually implemented in x86 code as:

Listing 1.309: x86

```
; CL=n
MOV REG, 1
SHL REG, CL
AND input_value, REG
```

Set specific bit (known at compile stage)

Listing 1.310: C/C++

```c
value=value|0x40;
```

Listing 1.311: x86

```
OR REG, 40h
```

Listing 1.312: ARM (ARM mode) and ARM64

```
ORR R0, R0, #0x40
```

Set specific bit (specified at runtime)

Listing 1.313: C/C++

```c
value=value|(1<<n);
```

This is usually implemented in x86 code as:

Listing 1.314: x86

```
; CL=n
MOV REG, 1
SHL REG, CL
OR input_value, REG
```
**Clear specific bit (known at compile stage)**

Just apply AND operation with the inverted value:

```c
value=value&(~0x40);
```

**Listing 1.315: C/C++**

```x86
AND REG, 0xFFFFFFBFh
```

**Listing 1.316: x86**

```x64
AND REG, 0xFFFFFFFFFFFFFFBFh
```

This is actually leaving all bits set except one.

ARM in ARM mode has BIC instruction, which works like the NOT + AND instruction pair:

```arm
BIC R0, R0, #0x40
```

**Listing 1.318: ARM (ARM mode)**

**Clear specific bit (specified at runtime)**

```c
value=value&(-(1<<n));
```

**Listing 1.319: C/C++**

```x86
; CL=n
MOV REG, 1
SHL REG, CL
NOT REG
AND input_value, REG
```

**Listing 1.320: x86**

### 1.28.7 Exercises

- [http://challenges.re/67](http://challenges.re/67)
- [http://challenges.re/68](http://challenges.re/68)
- [http://challenges.re/69](http://challenges.re/69)
- [http://challenges.re/70](http://challenges.re/70)

### 1.29 Linear congruential generator as pseudorandom number generator

Perhaps, the linear congruential generator is the simplest possible way to generate random numbers. It’s not in favour nowadays\(^{157}\), but it’s so simple (just one multiplication, one addition and AND operation), that we can use it as an example.

```c
#include <stdint.h>

// constants from the Numerical Recipes book
#define RNG_a 1664525
#define RNG_c 1013904223

static uint32_t rand_state;
```

\(^{157}\)Mersenne twister is better

(For statistics collecting purposes) if you’ve read this far, please click [here](http://challenges.re/67). Thanks!
void my_srand (uint32_t init)
{
    rand_state=init;
}

int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state+RNG_c;
    return rand_state & 0x7fff;
}

There are two functions: the first one is used to initialize the internal state, and the second one is called to generate pseudorandom numbers.

We see that two constants are used in the algorithm. They are taken from [William H. Press and Saul A. Teukolsky and William T. Vetterling and Brian P. Flannery, *Numerical Recipes*, (2007)].

Let's define them using a `#define` C/C++ statement. It's a macro.

The difference between a C/C++ macro and a constant is that all macros are replaced with their value by C/C++ preprocessor, and they don't take any memory, unlike variables.

In contrast, a constant is a read-only variable.

It's possible to take a pointer (or address) of a constant variable, but impossible to do so with a macro.

The last AND operation is needed because by C-standard `my_rand()` has to return a value in the 0..32767 range.

If you want to get 32-bit pseudorandom values, just omit the last AND operation.

### 1.29.1 x86

```plaintext
Listing 1.321: Optimizing MSVC 2013

_BSS SEGMENT
_rand_state DD 01H DUP (?)
_BSS ENDS

_init$ = 8
_srand PROC
    mov eax, DWORD PTR _init$[esp-4]
    mov DWORD PTR _rand_state, eax
    ret
_srand ENDP

_TEXT SEGMENT
_rand PROC
    imul eax, DWORD PTR _rand_state, 1664525
    add eax, 1013904223 ; 3c6ef35fH
    mov DWORD PTR _rand_state, eax
    and eax, 32767 ; 00007fffH
    ret
_rand ENDP

(TEXT ENDS

 Here we see it: both constants are embedded into the code. There is no memory allocated for them.

The `my_srand()` function just copies its input value into the internal `rand_state` variable.

`my_rand()` takes it, calculates the next `rand_state`, cuts it and leaves it in the EAX register.

The non-optimized version is more verbose:

Listing 1.322: Non-optimizing MSVC 2013

_BSS SEGMENT
_rand_state DD 01H DUP (?)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
1.29.2 x64

The x64 version is mostly the same and uses 32-bit registers instead of 64-bit ones (because we are working with \textit{int} values here).

But \texttt{my\_srand()} takes its input argument from the ECX register rather than from stack:

\begin{verbatim}
    _TEXT SEGMENT
    _rand PROC
    push ebp
    mov ebp, esp
    imul eax, DWORD PTR _rand_state, 1664525
    mov DWORD PTR _rand_state, eax
    add ecx, 1013904223 ; 3c6ef35fH
    mov DWORD PTR _rand_state, ecx
    mov eax, DWORD PTR _rand_state
    and eax, 32767 ; 00007fffH
    ret 0
    _rand ENDP

    _TEXT ENDS
\end{verbatim}

GCC compiler generates mostly the same code.

1.29.3 32-bit ARM

\begin{verbatim}
    _TEXT SEGMENT
    my\_rand PROC
    imul eax, DWORD PTR rand_state, 1664525 ; 0019660dH
    add eax, 1013904223 ; 3c6ef35fH
    mov DWORD PTR rand_state, eax
    and eax, 32767 ; 00007fffH
    ret 0
    my\_rand ENDP

    _TEXT ENDS
\end{verbatim}

(For statistics collecting purposes) if you’ve read this far, please click \url{here}. Thanks!
my_srand PROC
LDR r1,[L0.52] ; load pointer to rand_state
STR r0,[r1,#0] ; save rand_state
BX lr
ENDP

my_rand PROC
LDR r0,[L0.52] ; load pointer to rand_state
LDR r2,[L0.56] ; load RNG_a

rand_state
DCD 0x00000000

It’s not possible to embed 32-bit constants into ARM instructions, so Keil has to place them externally and load them additionally. One interesting thing is that it’s not possible to embed the 0x7FFF constant as well. So what Keil does is shifting rand_state left by 17 bits and then shifting it right by 17 bits. This is analogous to the \((\text{rand\_state} \ll 17) \gg 17\) statement in C/C++. It seems to be useless operation, but what it does is clearing the high 17 bits, leaving the low 15 bits intact, and that’s our goal after all.

Optimizing Keil for Thumb mode generates mostly the same code.

1.29.4 MIPS

Listing 1.325: Optimizing GCC 4.4.5 (IDA)

my_srando to rand_state:
  lui $v0, (rand_state >> 16)
  jr $ra
  sw $a0, rand_state

my_rand:
; Load rand_state to $v0:
  lui $v1, (rand_state >> 16)
  lw $v0, rand_state
  or $at, $zero ; load delay slot
; multiplicate rand_state in $v0 by 1664525 (RNG_a):
  sll $a1, $v0, 2
  sll $a0, $v0, 4
  addu $a0, $a1, $a0
  sll $a1, $a0, 6
  subu $a0, $a1, $a0
  addu $a0, $v0
  sll $a1, $a0, 5
  addu $a0, $a1
  sll $a0, 3
  addu $v0, $a0, $v0
  sll $a0, $v0, 2
  addu $v0, $a0

; add 1013904223 (RNG_c)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Wow, here we see only one constant (0x3C6EF35F or 1013904223). Where is the other one (1664525)? It seems that multiplication by 1664525 is performed by just using shifts and additions! Let’s check this assumption:

```c
#define RNG_a 1664525

int f (int a)
{
    return a*RNG_a;
}
```

Indeed!

**MIPS relocations**

We will also focus on how such operations as load from memory and store to memory actually work. The listings here are produced by IDA, which hides some details. We’ll run objdump twice: to get a disassembled listing and also relocations list:

```bash
# objdump -D rand_O3.o
...
00000000 <my_srand>:
  0: 3c020000 lui v0,0x0
  4: 03e00008 jr ra
  8: ac440000 sw a0,0(v0)

00000000c <my_rand>:
  c: 3c030000 lui v1,0x0
  10: 8c620000 lw v0,0(v1)
  14: 00200825 move at,at
  18: 00022880 sll a1,v0,0x2
  1c: 00022100 sll a0,v0,0x4
  20: 00a42021 addu a0,a1,a0
  24: 00042980 sll a1,a0,0x6
  28: 00a42023 subu a0,a1,a0
  2c: 00822021 addu a0,a0,v0
  30: 00042940 sll a1,a0,0x5
  34: 00852021 addu a0,a0,a1
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let’s consider the two relocations for the `my_srand()` function.

The first one, for address 0 has a type of R_MIPS_HI16 and the second one for address 8 has a type of R_MIPS_LO16.

That implies that address of the beginning of the .bss segment is to be written into the instructions at address of 0 (high part of address) and 8 (low part of address).

The `rand_state` variable is at the very start of the .bss segment.

So we see zeros in the operands of instructions LUI and SW, because nothing is there yet— the compiler don’t know what to write there.

The linker will fix this, and the high part of the address will be written into the operand of LUI and the low part of the address—to the operand of SW.

SW will sum up the low part of the address and what is in register $V0 (the high part is there).

It’s the same story with the `my_rand()` function: R_MIPS_HI16 relocation instructs the linker to write the high part of the .bss segment address into instruction LUI.

So the high part of the rand_state variable address is residing in register $V1.

The LW instruction at address 0x10 sums up the high and low parts and loads the value of the rand_state variable into $V0.

The SW instruction at address 0x54 do the summing again and then stores the new value to the rand_state global variable.

IDA processes relocations while loading, thus hiding these details, but we should keep them in mind.

1.29.5 Thread-safe version of the example

The thread-safe version of the example is to be demonstrated later: 6.2.1 on page 742.

1.30 Structures

A C/C++ structure, with some assumptions, is just a set of variables, always stored in memory together, not necessary of the same type \(^{158}\).

\(^{158}\) AKA “heterogeneous container”
1.30.1 MSVC: SYSTEMTIME example

Let's take the SYSTEMTIME\textsuperscript{159} win32 structure that describes time.

This is how it's defined:

```
Listing 1.328: WinBase.h

typedef struct _SYSTEMTIME {
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *PSYSTEMTIME;
```

Let's write a C function to get the current time:

```c
#include <windows.h>
#include <stdio.h>

void main()
{
    SYSTEMTIME t;
    GetSystemTime (&t);
    printf("%04d-%02d-%02d %02d:%02d:%02d\n",
        t.wYear, t.wMonth, t.wDay,
        t.wHour, t.wMinute, t.wSecond);
    return;
}
```

We get (MSVC 2010):

```
Listing 1.329: MSVC 2010 /GS-
t$ = -16 ; size = 16
main PROC
    push ebp
    mov ebp, esp
    sub esp, 16
    lea eax, DWORD PTR _t$[ebp]
    push eax
    call DWORD PTR _imp_GetSystemTime@4
    movzx ecx, WORD PTR _t$[ebp+12] ; wSecond
    push ecx
    movzx edx, WORD PTR _t$[ebp+10] ; wMinute
    push edx
    movzx eax, WORD PTR _t$[ebp+8] ; wHour
    push eax
    movzx ecx, WORD PTR _t$[ebp+6] ; wDay
    push ecx
    movzx edx, WORD PTR _t$[ebp+2] ; wMonth
    push edx
    movzx eax, WORD PTR _t$[ebp] ; wYear
    push eax
    push OFFSET $SG78811 ; '%04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H
    call _printf
    add esp, 28
    xor eax, eax
    mov esp, ebp
    pop ebp
    ret 0
main ENDP
```

\textsuperscript{159}MSDN: SYSTEMTIME structure

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
16 bytes are allocated for this structure in the local stack — that is exactly sizeof(WORD)*8 (there are 8 WORD variables in the structure).

Pay attention to the fact that the structure begins with the wYear field. It can be said that a pointer to the SYSTEMTIME structure is passed to the GetSystemTime()\(^\text{160}\), but it is also can be said that a pointer to the wYear field is passed, and that is the same! GetSystemTime() writes the current year to the WORD pointer pointing to, then shifts 2 bytes ahead, writes current month, etc., etc.

\(^{160}\text{MSDN: SYSTEMTIME structure}\)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's compile this example in MSVC 2010 with /GS- /MD keys and run it in OllyDbg.

Let's open windows for data and stack at the address which is passed as the first argument of the `GetSystemTime()` function, and let's wait until it's executed. We see this:

![Figure 1.105: OllyDbg: GetSystemTime() just executed](image)

The system time of the function execution on my computer is 9 December 2014, 22:29:52:

```
Listing 1.330: printf() output
2014-12-09 22:29:52
```

So we see these 16 bytes in the data window:

```
DE 07 0C 00 02 00 09 00 16 00 1D 00 34 00 D4 03
```

Each two bytes represent one field of the structure. Since the endianness is little endian, we see the low byte first and then the high one.

Hence, these are the values currently stored in memory:

<table>
<thead>
<tr>
<th>Hexadecimal number</th>
<th>decimal number</th>
<th>field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x07DE</td>
<td>2014</td>
<td>wYear</td>
</tr>
<tr>
<td>0x000C</td>
<td>12</td>
<td>wMonth</td>
</tr>
<tr>
<td>0x0002</td>
<td>2</td>
<td>wDayOfWeek</td>
</tr>
<tr>
<td>0x0009</td>
<td>9</td>
<td>wDay</td>
</tr>
<tr>
<td>0x0016</td>
<td>22</td>
<td>wHour</td>
</tr>
<tr>
<td>0x001D</td>
<td>29</td>
<td>wMinute</td>
</tr>
<tr>
<td>0x0034</td>
<td>52</td>
<td>wSecond</td>
</tr>
<tr>
<td>0x03D4</td>
<td>980</td>
<td>wMilliseconds</td>
</tr>
</tbody>
</table>

The same values are seen in the stack window, but they are grouped as 32-bit values.

And then `printf()` just takes the values it needs and outputs them to the console.

Some values aren't output by `printf()` (wDayOfWeek and wMilliseconds), but they are in memory right now, available for use.

### Replacing the structure with array

The fact that the structure fields are just variables located side-by-side, can be easily demonstrated by doing the following. Keeping in mind the SYSTEMTIME structure description, it's possible to rewrite this
simple example like this:

```c
#include <windows.h>
#include <stdio.h>

void main()
{
    WORD array[8];
    GetSystemTime (array);

    printf("%04d-%02d-%02d %02d:%02d:%02d\n",
           array[0] /* wYear */, array[1] /* wMonth */, array[3] /* wDay */,
    return;
}
```

The compiler grumbles a bit:

```
systemtime2.c(7) : warning C4133: 'function' : incompatible types - from 'WORD [8]' to '⤦
⤦
⤦
⤦\LPSYSTEMTIME'
```

But nevertheless, it produces this code:

Listing 1.331: Non-optimizing MSVC 2010

```
$SG78573 DB ' %04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H
_array$ = -16 ; size = 16
_main PROC
    push ebp
    mov ebp, esp
    sub esp, 16
    lea eax, DWORD PTR _array$[ebp]
    push eax
    call DWORD PTR __imp__GetSystemTime@4
    movzx ecx, DWORD PTR _array$[ebp+12] ; wSecond
    push ecx
    movzx edx, DWORD PTR _array$[ebp+10] ; wMinute
    push edx
    movzx eax, DWORD PTR _array$[ebp+8] ; wHour
    push eax
    movzx ecx, DWORD PTR _array$[ebp+6] ; wDay
    push ecx
    movzx edx, DWORD PTR _array$[ebp+2] ; wMonth
    push edx
    movzx eax, DWORD PTR _array$[ebp] ; wYear
    push eax
    push OFFSET $SG78573 ; ' %04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H
    call _printf
    add esp, 28
    xor eax, eax
    mov esp, ebp
    pop ebp
    ret 0
_main ENDP
```

And it works just as the same!

It is very interesting that the result in assembly form cannot be distinguished from the result of the previous compilation.

So by looking at this code, one cannot say for sure if there was a structure declared, or an array.

Nevertheless, no sane person would do it, as it is not convenient.

Also the structure fields may be changed by developers, swapped, etc.

We will not study this example in OllyDbg, because it will be just the same as in the case with the structure.
1.30.2 Let’s allocate space for a structure using malloc()

Sometimes it is simpler to place structures not in the local stack, but in the heap:

```c
#include <windows.h>
#include <stdio.h>

void main()
{
    SYSTEMTIME *t;
    t=(SYSTEMTIME *)malloc (sizeof (SYSTEMTIME));
    GetSystemTime (t);
    printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
            t->wYear, t->wMonth, t->wDay,
            t->wHour, t->wMinute, t->wSecond);
    free (t);
    return;
}
```

Let’s compile it now with optimization (/Ox) so it would be easy to see what we need.

```
Listing 1.332: Optimizing MSVC

main PROC
push esi
push 16
call _malloc
add esp, 4
mov esi, eax
push esi
call DWORD PTR __imp__GetSystemTime@4
movzx eax, WORD PTR [esi+12]; wSecond
movzx ecx, WORD PTR [esi+10]; wMinute
movzx edx, WORD PTR [esi+8]; wHour
push eax
movzx eax, WORD PTR [esi+6]; wDay
push ecx
movzx ecx, WORD PTR [esi+2]; wMonth
push edx
movzx edx, WORD PTR [esi]; wYear
push eax
push ecx
push edx
push OFFSET $SG78833
call _printf
push esi
call _free
add esp, 32
xor eax, eax
pop esi
ret 0
main ENDP
```

So, sizeof(SYSTEMTIME) = 16 and that is exact number of bytes to be allocated by malloc(). It returns a pointer to a freshly allocated memory block in the EAX register, which is then moved into the ESI register. GetSystemTime() win32 function takes care of saving value in ESI, and that is why it is not saved here and continues to be used after the GetSystemTime() call.

New instruction —MOVZX (Move with Zero eXtend). It may be used in most cases as MOVsx, but it sets the remaining bits to 0. That’s because printf() requires a 32-bit int, but we got a WORD in the structure — that is 16-bit unsigned type. That’s why by copying the value from a WORD into int, bits from 16 to 31 must be cleared, because a random noise may be there, which is left from the previous operations on the register(s).

In this example, it’s possible to represent the structure as an array of 8 WORDs:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
#include <windows.h>
#include <stdio.h>

void main()
{
    WORD *t;
    t=(WORD *)malloc (16);
    GetSystemTime (t);
    free (t);
    return (t);
};
```

We get:

Listing 1.333: Optimizing MSVC

```
$SG78594 DB '%04d-%02d-%02d %02d:%02d:%02d', 0AH, 00H

_main PROC
    push esi
    push 16
    call _malloc
    add esp, 4
    mov esi, eax
    push esi
    call DWORD PTR __imp__GetSystemTime@4
    movzx eax, WORD PTR [esi+12]
    movzx ecx, WORD PTR [esi+10]
    movzx edx, WORD PTR [esi+8]
    push eax
    movzx eax, WORD PTR [esi+6]
    push ecx
    movzx ecx, WORD PTR [esi+2]
    push edx
    movzx edx, WORD PTR [esi]
    push eax
    push ecx
    push ecx
    push ecx
    push OFFSET $SG78594
    call _printf
    push esi
    call _free
    add esp, 32
    xor eax, eax
    pop esi
    ret 0

_main ENDP
```

Again, we got the code that cannot be distinguished from the previous one.

And again it has to be noted, you haven’t to do this in practice, unless you really know what you are doing.

### 1.30.3 UNIX: struct tm

**Linux**

Let’s take the `tm` structure from `time.h` in Linux for example:

```c
#include <stdio.h>
#include <time.h>
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
void main()
{
    struct tm t;
    time_t unix_time;

    unix_time=time(NULL);
    localtime_r(&unix_time, &t);

    printf("Year: %d\n", t.tm_year+1900);
    printf("Month: %d\n", t.tm_mon);
    printf("Day: %d\n", t.tm_mday);
    printf("Hour: %d\n", t.tm_hour);
    printf("Minutes: %d\n", t.tm_min);
    printf("Seconds: %d\n", t.tm_sec);
}
```

Let's compile it in GCC 4.4.1:

```assembly
main proc near
    push ebp
    mov ebp, esp
    and esp, 0FFFFFFF0h
    sub esp, 40h
    mov dword ptr [esp], 0 ; first argument for time()
    call time
    mov [esp+3Ch], eax
    lea eax, [esp+3Ch] ; take pointer to what time() returned
    lea edx, [esp+10h] ; at ESP+10h struct tm will begin
    mov [esp+4], edx ; pass pointer to the structure begin
    mov [esp], eax ; pass pointer to result of time()
    call localtime_r
    mov eax, [esp+24h] ; tm_year
    lea edx, [eax+76Ch] ; edx=eax+1900
    mov eax, offset format ; "Year: %d"
    mov [esp+4], edx
    mov [esp], eax
    call printf
    mov edx, [esp+20h] ; tm_mon
    mov eax, offset aMonthD ; "Month: %d"
    mov [esp+4], edx
    mov [esp], eax
    call printf
    mov edx, [esp+1Ch] ; tm_mday
    mov eax, offset aDayD ; "Day: %d"
    mov [esp+4], edx
    mov [esp], eax
    call printf
    mov edx, [esp+18h] ; tm_hour
    mov eax, offset aHourD ; "Hour: %d"
    mov [esp+4], edx
    mov [esp], eax
    call printf
    mov edx, [esp+14h] ; tm_min
    mov eax, offset aMinutesD ; "Minutes: %d"
    mov [esp+4], edx
    mov [esp], eax
    call printf
    mov edx, [esp+10h]
    mov eax, offset aSecondsD ; "Seconds: %d"
    mov [esp+4], edx ; tm_sec
    mov [esp], eax
    call printf
    leave
    ret
main endp
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Somehow, IDA did not write the local variables’ names in the local stack. But since we already are experienced reverse engineers :-) we may do it without this information in this simple example.

Please also pay attention to the `lea edx, [eax+76Ch]`—this instruction just adds 0x76C (1900) to value in EAX, but doesn’t modify any flags. See also the relevant section about LEA (.1.6 on page 1001).

GDB

Let’s try to load the example into GDB:

---

**Listing 1.335: GDB**

dennis@ubuntuvm:~/polygon$ date
Mon Jun 2 18:10:37 EEST 2014
dennis@ubuntuvm:~/polygon$ gcc GCC_tm.c -o GCC_tm
dennis@ubuntuvm:~/polygon$ gdb GCC_tm
GNU gdb (GDB) 7.6.1-ubuntu ...
Reading symbols from /home/dennis/polygon/GCC_tm...(no debugging symbols found)...done.
(gdb) b printf
Breakpoint 1 at 0x8048330
(gdb) run
Starting program: /home/dennis/polygon/GCC_tm
Breakpoint 1, __printf (format=0x80485c0 "Year: %d\n") at printf.c:29
29 printf.c: No such file or directory.
(gdb) x/20x $esp
0xbffff0dc: 0x080484c3 0x080485c0 0x000007de 0x00000000
0xbffff0ec: 0x08048301 0x538c93ed 0x00000025 0x0000000a
0xbffff0fc: 0x00000012 0x00000002 0x00000005 0x00000072
0xbffff10c: 0x00000001 0x00000098 0x00000001 0x00002a30
0xbffff11c: 0x0804b090 0x08048530 0x00000000 0x00000000
(gdb)

---

We can easily find our structure in the stack. First, let’s see how it’s defined in `time.h`:

---

**Listing 1.336: time.h**

```
struct tm {
    int tm_sec;
    int tm_min;
    int tm_hour;
    int tm_mday;
    int tm_mon;
    int tm_year;
    int tm_wday;
    int tm_yday;
    int tm_isdst;
};
```

---

Pay attention that 32-bit `int` is used here instead of `WORD` in `SYSTEMTIME`. So, each field occupies 32-bit. Here are the fields of our structure in the stack:

```
0xbffff0dc: 0x080484c3 0x080485c0 0x0000007de 0x00000000
0xbffff0ec: 0x08048301 0x538c93ed 0x00000025 0x0000000a
0xbffff0fc: 0x00000012 0x00000002 0x00000005 0x00000072
0xbffff10c: 0x00000001 0x00000098 0x00000001 0x00002a30
0xbffff11c: 0x0804b090 0x08048530 0x00000000 0x00000000
```

Or as a table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value 1</th>
<th>Value 2</th>
<th>Value 3</th>
<th>Value 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>tm_sec</td>
<td>0x080484c3</td>
<td>0x080485c0</td>
<td>0x0000007de</td>
<td>0x00000000</td>
</tr>
<tr>
<td>tm_min</td>
<td>0x08048301</td>
<td>0x538c93ed</td>
<td>0x00000025</td>
<td>0x0000000a</td>
</tr>
<tr>
<td>tm_hour</td>
<td>0x00000012</td>
<td>0x00000002</td>
<td>0x00000005</td>
<td>0x00000072</td>
</tr>
<tr>
<td>tm_mday</td>
<td>0x00000001</td>
<td>0x00000098</td>
<td>0x00000001</td>
<td>0x00002a30</td>
</tr>
<tr>
<td>tm_mon</td>
<td>0x0804b090</td>
<td>0x08048530</td>
<td>0x00000000</td>
<td>0x00000000</td>
</tr>
</tbody>
</table>

---

The `date` result is slightly corrected for demonstration purposes. Of course, it’s not possible to run GDB that quickly, in the same second.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
<table>
<thead>
<tr>
<th>Hexadecimal number</th>
<th>decimal number</th>
<th>field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000000025</td>

$LC2: .ascii "Day: %d\n"<0>
$LC3: .ascii "Hour: %d\n"<0>
$LC4: .ascii "Minutes: %d\n"<0>
This is an example where the branch delay slots can confuse us.
For example, there is the instruction `addiu $a1, 1900` at line 35 which adds 1900 to the year number.
It's executed before the corresponding JALR at line 34, do not forget about it.

**Structure as a set of values**

In order to illustrate that the structure is just variables laying side-by-side in one place, let’s rework our example while looking at the `tm` structure definition again: listing 1.336.

```c
#include <stdio.h>
#include <time.h>

void main()
{
  int tm_sec, tm_min, tm_hour, tm_mday, tm_mon, tm_year, tm_wday, tm_yday, tm_isdst;
  time_t unix_time;

  unix_time=time(NULL);
  localtime_r (&unix_time, &tm_sec);

  printf("Year: %d\n", tm_year+1900);
  printf("Month: %d\n", tm_mon);
  printf("Day: %d\n", tm_mday);
  printf("Hour: %d\n", tm_hour);
  printf("Minutes: %d\n", tm_min);
  printf("Seconds: %d\n", tm_sec);
}
```

N.B. The pointer to the `tm_sec` field is passed into `localtime_r`, i.e., to the first element of the “structure”. The compiler warns us:

```
Listing 1.340: GCC 4.7.3
GCC_tm2.c: In function 'main':
GCC_tm2.c:11:5: warning: passing argument 2 of 'localtime_r' from incompatible pointer type
In file included from GCC_tm2.c:2:0:
/usr/include/time.h:59:12: note: expected 'struct tm *' but argument is of type 'int *'
But nevertheless, it generates this:
```

```
Listing 1.341: GCC 4.7.3
main proc near
var_30 = dword ptr -30h
var_2C = dword ptr -2Ch
unix_time = dword ptr -1Ch
tm_sec = dword ptr -18h
tm_min = dword ptr -14h
tm_hour = dword ptr -10h
tm_mday = dword ptr -0Ch
tm_mon = dword ptr -8
tm_year = dword ptr -4

push  ebp
mov ebp, esp
and esp, 0FFFFFF0h
sub esp, 30h
call __main
mov [esp+30h+var_30], 0 ; arg 0
call time
mov [esp+30h+unix_time], eax
lea eax, [esp+30h+tm_sec]
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This code is identical to what we saw previously and it is not possible to say, was it a structure in original source code or just a pack of variables.

And this works. However, it is not recommended to do this in practice.

Usually, non-optimizing compilers allocates variables in the local stack in the same order as they were declared in the function.

Nevertheless, there is no guarantee.

By the way, some other compiler may warn about the `tm_year`, `tm_mon`, `tm_mday`, `tm_hour`, `tm_min` variables, but not `tm_sec` are used without being initialized.

Indeed, the compiler is not aware that these are to be filled by `localtime_r()` function.

We chose this example, since all structure fields are of type `int`.

This would not work if structure fields are 16-bit (WORD), like in the case of the SYSTEMTIME structure—`GetSystemTime()` will fill them incorrectly (because the local variables are aligned on a 32-bit boundary). Read more about it in next section: "Fields packing in structure" (1.30.4 on page 362).

So, a structure is just a pack of variables laying in one place, side-by-side. We could say that the structure is the instruction to the compiler, directing it to hold variables in one place. By the way, in some very early C versions (before 1972), there were no structures at all [Dennis M. Ritchie, The development of the C language, (1993)].

There is no debugger example here: it is just the same as you already saw.

### Structure as an array of 32-bit words

```c
#include <stdio.h>
#include <time.h>

void main()
{

162 Also available as http://go.yurichev.com/17264
```

(For statistics collecting purposes) if you’ve read this far, please click [here](http://go.yurichev.com/17264). Thanks!
struct tm t;
time_t unix_time;
int i;

unix_time=time(NULL);
localtime_r (&unix_time, &t);
for (i=0; i<9; i++)
{
    int tmp=((int*)&t)[i];
    printf("0x%08X (%d)\n", tmp, tmp);
}

We just cast a pointer to structure to an array of int's. And that works! We run the example at 23:51:45 26-July-2014.

0x0000002D (45)
0x00000033 (51)
0x00000017 (23)
0x0000001A (26)
0x00000006 (6)
0x00000072 (114)
0x00000006 (6)
0x000000CE (206)
0x00000001 (1)

The variables here are in the same order as they are enumerated in the definition of the structure: 1.336 on page 354.

Here is how it gets compiled:

Listing 1.342: Optimizing GCC 4.8.1

main proc near
    push ebp
    mov ebp, esp
    push esi
    push ebx
    and esp, 0FFFFFFF0h
    sub esp, 40h
    mov dword ptr [esp], 0 ; timer
    lea ebx, [esp+14h]
    call _time
    lea esi, [esp+38h]
    mov [esp+4], ebx ; tp
    mov [esp+10h], eax
    lea eax, [esp+10h]
    mov [esp], eax ; timer
    call _localtime_r
    nop
    lea esi, [esi+0] ; NOP

loc_80483D8:
; EBX here is pointer to structure, ESI is the pointer to the end of it.
    mov eax, [ebx] ; get 32-bit word from array
    add ebx, 4 ; next field in structure
    mov dword ptr [esp+4], offset a0x08x0D ; "0x%08X (%d)\n"
    mov dword ptr [esp], 1
    mov [esp+0Ch], eax ; pass value to printf()
    mov [esp+8], eax ; pass value to printf()
    call __printf_chk
    cmp ebx, esi ; meet structure end?
    jnz short loc_80483D8 ; no - load next value then
    lea esp, [ebp-8]
    pop ebx
    pop esi
    pop ebp
    retn
main endp
Indeed: the space in the local stack is first treated as a structure, and then it’s treated as an array. It’s even possible to modify the fields of the structure through this pointer. And again, it’s dubiously hackish way to do things, not recommended for use in production code.

Exercise

As an exercise, try to modify (increase by 1) the current month number, treating the structure as an array.

Structure as an array of bytes

We can go even further. Let’s cast the pointer to an array of bytes and dump it:

```c
#include <stdio.h>
#include <time.h>

void main()
{
    struct tm t;
    time_t unix_time;
    int i, j;
    unix_time=time(NULL);
    localtime_r (&unix_time, &t);
    for (i=0; i<9; i++)
    {
        for (j=0; j<4; j++)
            printf ("0x%02X ", ((unsigned char*)&t)[i*4+j]);
    }
};
```

```
0x2D 0x00 0x00 0x00
0x33 0x00 0x00 0x00
0x17 0x00 0x00 0x00
0x1A 0x00 0x00 0x00
0x06 0x00 0x00 0x00
0x72 0x00 0x00 0x00
0x06 0x00 0x00 0x00
0xCE 0x00 0x00 0x00
0x01 0x00 0x00 0x00
```

We also run this example at 23:51:45 26-July-2014. The values are just the same as in the previous dump (1.30.3 on the preceding page), and of course, the lowest byte goes first, because this is a little-endian architecture (2.8 on page 469).

Listing 1.343: Optimizing GCC 4.8.1

```
main proc near
    push ebp
    mov ebp, esp
    push edi
    push esi
    push ebx
    and esp, 0FFFFFFF0h
    sub esp, 40h
    mov dword ptr [esp], 0 ; timer
    lea esi, [esp+14h]
    call _time
    lea edi, [esp+38h] ; struct end
    mov [esp+4], esi ; tp
    mov [esp+10h], eax
```

163The time and date are the same for demonstration purposes. Byte values are fixed up.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
leahl eax, [esp+10h]
movl [esp], eax ; timer
call _localtime_r
lea esi, [esi+0] ; NOP

ESI here is the pointer to structure in local stack. EDI is the pointer to structure end.

loc_8048408:
xor ebx, ebx ; j=0

loc_804840A:
movzx eax, byte ptr [esi+ebx] ; load byte
add ebx, 1 ; j=j+1
mov dword ptr [esp+4], offset a0x02x ; "0x%02X"
mov dword ptr [esp], 1
mov [esp+8], eax ; pass loaded byte to printf()
call ___printf_chk
cmp ebx, 4
jnz short loc_804840A

; print carriage return character (CR)
mov dword ptr [esp], 0Ah ; c
add esi, 4
call _putchar
cmp esi, edi ; meet struct end?
jnz short loc_8048408
lea esp, [ebp-0Ch]
pop ebx
pop esi
pop edi
pop ebp
retn

main endp

GNU Scientific Library: Representation of complex numbers

This is a relatively rare case when an array is used instead of a structure, on purpose:

Representation of complex numbers
==================================
Complex numbers are represented using the type :code:`gsl_complex`. The internal representation of this type may vary across platforms and should not be accessed directly. The functions and macros described below allow complex numbers to be manipulated in a portable way.

For reference, the default form of the :code:`gsl_complex` type is given by the following struct:

```c
typedef struct
{
 double dat[2];
} gsl_complex;
```

The real and imaginary part are stored in contiguous elements of a two element array. This eliminates any padding between the real and imaginary parts, :code:`'dat[0]'` and :code:`'dat[1]'`, allowing the struct to be mapped correctly onto packed complex arrays.

### 1.30.4 Fields packing in structure

One important thing is fields packing in structures\(^\text{164}\).

Let's take a simple example:

\(^\text{164}\)See also: Wikipedia: Data structure alignment
```c
#include <stdio.h>

struct s {
    char a;
    int b;
    char c;
    int d;
};

void f(struct s s) {
    printf("a=%d; b=%d; c=%d; d=%d\n", s.a, s.b, s.c, s.d);
}

int main() {
    struct s tmp;
    tmp.a=1;
    tmp.b=2;
    tmp.c=3;
    tmp.d=4;
    f(tmp);
}
```

As we see, we have two char fields (each is exactly one byte) and two more — int (each — 4 bytes).

**x86**

This compiles to:

```c
.timedelta=3.01549
_d::_main PROC
	_push ebp
	mov ebp, esp
	sub esp, 16
	mov BYTE PTR _tmp$[ebp], 1 ; set field a
	mov DWORD PTR _tmp$[ebp+4], 2 ; set field b
	mov BYTE PTR _tmp$[ebp+8], 3 ; set field c
	mov DWORD PTR _tmp$[ebp+12], 4 ; set field d
	sub esp, 16 ; allocate place for temporary structure
	mov eax, esp
	mov ecx, DWORD PTR _tmp$[ebp] ; copy our structure to the temporary one
	mov edx, DWORD PTR _tmp$[ebp+4]
	mov edx, DWORD PTR _tmp$[ebp+4]
	mov edx, DWORD PTR _tmp$[ebp+4]
	mov edx, DWORD PTR _tmp$[ebp+4]
	call f
	add esp, 16
	xor eax, eax
	mov esp, ebp
	pop ebp
	ret 0
_d::_main ENDP
.timedelta=3.01549
dw size$ = 8 ; size = 16
?f@@YAXUs@@@Z PROC ; f
	_push ebp
	mov ebp, esp
	mov eax, DWORD PTR _s$[ebp+12]
	push eax
	movsx ecx, BYTE PTR _s$[ebp+8]
	push ecx
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We pass the structure as a whole, but in fact, as we can see, the structure is being copied to a temporary one (a place in stack is allocated in line 10 for it, and then all 4 fields, one by one, are copied in lines 12 ... 19), and then its pointer (address) is to be passed.

The structure is copied because it’s not known whether the f() function going to modify the structure or not. If it gets changed, then the structure in main() has to remain as it has been.

We could use C/C++ pointers, and the resulting code will be almost the same, but without the copying.

As we can see, each field’s address is aligned on a 4-byte boundary. That’s why each char occupies 4 bytes here (like int). Why? Because it is easier for the CPU to access memory at aligned addresses and to cache data from it.

However, it is not very economical.

Let's try to compile it with option (/Zp1) (/Zp[n] pack structures on n-byte boundary).

Listing 1.345: MSVC 2012 /GS- /Zp1

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now the structure takes only 10 bytes and each char value takes 1 byte. What does it give to us? Size economy. And as drawback—the CPU accessing these fields slower than it could.

The structure is also copied in main(). Not field-by-field, but directly 10 bytes, using three pairs of MOV. Why not 4?

The compiler decided that it’s better to copy 10 bytes using 3 MOV pairs than to copy two 32-bit words and two bytes using 4 MOV pairs.

By the way, such copy implementation using MOV instead of calling the memcpy() function is widely used, because it’s faster than a call to memcpy()—for short blocks, of course: 3.12.1 on page 518.

As it can be easily guessed, if the structure is used in many source and object files, all these must be compiled with the same convention about structures packing.

Aside from MSVC /Zp option which sets how to align each structure field, there is also the #pragma pack compiler option, which can be defined right in the source code. It is available in both MSVC and GCC.

Let’s get back to the SYSTEMTIME structure that consists of 16-bit fields. How does our compiler know to pack them on 1-byte alignment boundary?

WinNT.h file has this:

Listing 1.346: WinNT.h

```
#include "pshpack1.h"
```

And this:

Listing 1.347: WinNT.h

```
#include "pshpack4.h"  // 4 byte packing is the default
```

The file PshPack1.h looks like:

Listing 1.348: PshPack1.h

```
#if ! (defined(lint) || defined(RC_INVOKED))
#elif (!defined(_M_I86)) || defined(_PUSHPOP_SUPPORTED)
#elif !defined( MIDL_PASS ) || defined( __midl )
#pragma pack(push,1)
#else
#pragma pack(1)
#endif
#else
#pragma pack(1)
#endif
#endif /* ! (defined(lint) || defined(RC_INVOKED)) */
```

This tell the compiler how to pack the structures defined after #pragma pack.
Let's try our example (where the fields are aligned by default (4 bytes)) in OllyDbg:

![OllyDbg output](image)

Figure 1.106: OllyDbg: Before printf() execution

We see our 4 fields in the data window.

But where do the random bytes (0x30, 0x37, 0x01) come from, that are next to the first (a) and third (c) fields?

By looking at our listing 1.344 on page 363, we can see that the first and third fields are char, therefore only one byte is written, 1 and 3 respectively (lines 6 and 8).

The remaining 3 bytes of the 32-bit words are not being modified in memory! Hence, random garbage is left there.

This garbage doesn’t influence the printf() output in any way, because the values for it are prepared using the MOVSX instruction, which takes bytes, not words: listing.1.344 (lines 34 and 38).

By the way, the MOVSX (sign-extending) instruction is used here, because char is signed by default in MSVC and GCC. If the unsigned char data type or uint8_t was used here, MOVZX instruction would have been used instead.
367

OllyDbg + fields aligning on 1 byte boundary

Things are much clearer here: 4 fields occupy 10 bytes and the values are stored side-by-side

Figure 1.107: OllyDbg: Before printf() execution

ARM

Optimizing Keil 6/2013 (Thumb mode)

Listing 1.349: Optimizing Keil 6/2013 (Thumb mode)

As we may recall, here a structure is passed instead of pointer to one, and since the first 4 function arguments in ARM are passed via registers, the structure’s fields are passed via R0-R3.

LDRB loads one byte from memory and extends it to 32-bit, taking its sign into account. This is similar to MOVSX in x86. Here it is used to load fields a and c from the structure.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
One more thing we spot easily is that instead of function epilogue, there is jump to another function’s epilogue! Indeed, that was quite different function, not related in any way to ours, however, it has exactly the same epilogue (probably because, it hold 5 local variables too \((5 \times 4 = 0 \times 14)\)).

Also it is located nearby (take a look at the addresses).

Indeed, it doesn’t matter which epilogue gets executed, if it works just as we need.

Apparently, Keil decides to reuse a part of another function to economize.

The epilogue takes 4 bytes while jump—only 2.

**ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)**

### Listing 1.350: Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

```assembly
var_C = -0xC

PUSH {R7,LR}
MOV R7, SP
SUB SP, SP, #4
MOV R9, R1 ; b
MOV R1, R0 ; a
MOV R0, #0xF10 ; "a=%d; b=%d; c=%d; d=%d\n"
SXTB R1, R1 ; prepare a
MOVT W R0, #0
STR R3, [SP,#0x0+C+var_C] ; place d to stack for printf()
ADD R0, PC ; format-string
SXTB R3, R2 ; prepare c
MOV R2, R9 ; b
BLX _printf
ADD SP, SP, #4
POP {R7,PC}
```

SXTB (**Signed Extend Byte**) is analogous to **MOV$X** in x86. All the rest—just the same.

**MIPS**

### Listing 1.351: Optimizing GCC 4.4.5 (IDA)

```assembly
f:

var_18 = -0x18
var_10 = -0x10
var_4 = -4
arg_0 = 0
arg_4 = 4
arg_8 = 8
arg_C = 0xC

lui $gp, (__gnu_local_gp >> 16)
addiu $sp, -0x28
la $gp, (__gnu_local_gp & 0xFFFF)
sw $ra, 0x28+var_4($sp)
sw $gp, 0x28+var_10($sp)

; prepare a byte from 32-bit big-endian integer:
sra $t0, $a0, 24
move $v1, $a1

; prepare a byte from 32-bit big-endian integer:
sra $v0, $a2, 24
lw $t9, (printf & 0xFFFF)($gp)
sw $a0, 0x28+arg_0($sp)
lui $a0, ($LC0 >> 16) # "a=%d; b=%d; c=%d; d=%d\n"
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Structure fields come in registers $A0..A3 and then get reshuffled into $A1..A3 for printf(), while 4th field (from $A3) is passed via local stack using SW.

But there are two SRA (“Shift Word Right Arithmetic”) instructions, which prepare char fields. Why?

MIPS is a big-endian architecture by default 2.8 on page 469, and the Debian Linux we work in is big-endian as well.

So when byte variables are stored in 32-bit structure slots, they occupy the high 31..24 bits.

And when a char variable needs to be extended into a 32-bit value, it must be shifted right by 24 bits. char is a signed type, so an arithmetical shift is used here instead of logical.

One more word

Passing a structure as a function argument (instead of a passing pointer to structure) is the same as passing all structure fields one by one.

If the structure fields are packed by default, the f() function can be rewritten as:

```c
void f(char a, int b, char c, int d) {
    printf ("a=%d; b=%d; c=%d; d=%d\n", a, b, c, d);
}
```

And that leads to the same code.

1.30.5 Nested structures

Now what about situations when one structure is defined inside of another?

```c
#include <stdio.h>

struct inner_struct {
    int a;
    int b;
};

struct outer_struct {
    char a;
    int b;
    struct inner_struct c;
    char d;
    int e;
};

void f(struct outer_struct s) {
    printf ("a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d\n", 
            s.a, s.b, s.c.a, s.c.b, s.d, s.e);
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
int main()
{
    struct outer_struct s;
    s.a=1;
    s.b=2;
    s.c.a=100;
    s.c.b=101;
    s.d=3;
    s.e=4;
    f(s);
};

...in this case, both inner_struct fields are to be placed between the a,b and d,e fields of the outer_struct.
Let's compile (MSVC 2010):

Listing 1.352: Optimizing MSVC 2010 /Ob0

$SG2802 DB 'a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d', 0AH, 00H

_TEXT    SEGMENT
_s$ = 8
_f    PROC
    mov    eax, DWORD PTR _s$[esp+16]
    movsx  ecx, BYTE PTR _s$[esp+12]
    mov    edx, DWORD PTR _s$[esp+8]
    push   eax
    mov    eax, DWORD PTR _s$[esp+8]
    push   ecx
    mov    edx, DWORD PTR _s$[esp+8]
    push   eax
    push   ecx
    push   edx
    movsx  edx, BYTE PTR _s$[esp+8]
    push   eax
    push   ecx
    push   edx
    push OFFSET $SG2802 ;'a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d'
    call   _printf
    add esp, 28
    ret    0
_f    ENDP

_s$ = -24
main    PROC
    sub    esp, 24
    push   ebx
    push   esi
    push   edi
    mov    ecx, 2
    sub    esp, 24
    mov    eax, esp
    ; from this moment, EAX is synonymous to ESP:
    mov    BYTE PTR _s$[esp+60], 1
    mov    ebx, DWORD PTR _s$[esp+60]
    mov    DWORD PTR [eax], ebx
    mov    DWORD PTR [eax+4], ecx
    lea    edx, DWORD PTR [ecx+98]
    lea    esi, DWORD PTR [ecx+99]
    lea    edi, DWORD PTR [ecx+2]
    mov    DWORD PTR [eax+8], edx
    mov    BYTE PTR _s$[esp+76], 3
    mov    ecx, DWORD PTR _s$[esp+76]
    mov    DWORD PTR [eax+12], esi
    mov    DWORD PTR [eax+16], ecx
    mov    DWORD PTR [eax+20], edi
    call   _f
    add    esp, 24
    pop    edi
    pop    esi
    xor    eax, eax

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
One curious thing here is that by looking onto this assembly code, we do not even see that another structure was used inside of it! Thus, we would say, nested structures are unfolded into linear or one-dimensional structure.

Of course, if we replace the struct inner_struct c; declaration with struct inner_struct *c; (thus making a pointer here) the situation will be quite different.
Let's load the example into OllyDbg and take a look at outer_struct in memory:

![OllyDbg: Before printf() execution](image)

That's how the values are located in memory:

- **(outer_struct.a)** (byte) 1 + 3 bytes of random garbage;
- **(outer_struct.b)** (32-bit word) 2;
- **(inner_struct.a)** (32-bit word) 0x64 (100);
- **(inner_struct.b)** (32-bit word) 0x65 (101);
- **(outer_struct.d)** (byte) 3 + 3 bytes of random garbage;
- **(outer_struct.e)** (32-bit word) 4.

### 1.30.6 Bit fields in a structure

**CPUID example**

The C/C++ language allows to define the exact number of bits for each structure field. It is very useful if one needs to save memory space. For example, one bit is enough for a `bool` variable. But of course, it is not rational if speed is important.

Let's consider the CPUID instruction example. This instruction returns information about the current CPU and its features.

If the EAX is set to 1 before the instruction's execution, CPUID returning this information packed into the EAX register:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Stepping</td>
<td>Model</td>
<td>Processor Type</td>
<td>Extended Model</td>
<td>Extended Family</td>
</tr>
<tr>
<td>3:0</td>
<td>4 bits</td>
<td>7:4</td>
<td>11:8</td>
<td>13:12</td>
<td>19:16</td>
</tr>
<tr>
<td>27:20</td>
<td>8 bits</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

MSVC 2010 has CPUID macro, but GCC 4.4.1 does not. So let's make this function by ourselves for GCC with the help of its built-in assembler.

---

167 Wikipedia
168 More about internal GCC assembler

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
```c
#include <stdio.h>

#ifdef __GNUC__
static inline void cpuid(int code, int *a, int *b, int *c, int *d) {
    asm volatile("cpuid":"=a"(*a),"=b"(*b),"=c"(*c),"=d"(*d):"a"(code));
} #endif

#ifdef _MSC_VER
#include <intrin.h>
#endif

struct CPUID_1_EAX {
    unsigned int stepping:4;
    unsigned int model:4;
    unsigned int family_id:4;
    unsigned int processor_type:2;
    unsigned int reserved1:2;
    unsigned int extended_model_id:4;
    unsigned int extended_family_id:8;
    unsigned int reserved2:4;
};

int main() {
    struct CPUID_1_EAX *tmp;
    int b[4];

#ifdef _MSC_VER
    __cpuid(b,1);
#endif

#ifdef __GNUC__
    cpuid (1, &b[0], &b[1], &b[2], &b[3]);
#endif

tmp=(struct CPUID_1_EAX *)&b[0];

    printf("stepping=%d\n", tmp->stepping);
    printf("model=%d\n", tmp->model);
    printf("family_id=%d\n", tmp->family_id);
    printf("processor_type=%d\n", tmp->processor_type);
    printf("extended_model_id=%d\n", tmp->extended_model_id);
    printf("extended_family_id=%d\n", tmp->extended_family_id);
    return 0;
}
```

After CPUID fills EAX/EBX/ECX/EDX, these registers are to be written in the b[] array. Then, we have a pointer to the CPUID_1_EAX structure and we point it to the value in EAX from the b[] array.

In other words, we treat a 32-bit int value as a structure. Then we read specific bits from the structure.

**MSVC**

Let's compile it in MSVC 2008 with /Ox option:

```assembly
Listing 1.353: Optimizing MSVC 2008

main PROC
    sub    esp, 16
    push   ebx
    xor    ecx, ecx
    mov    eax, 1
    cpuid
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The SHR instruction shifting the value in EAX by the number of bits that must be skipped, e.g., we ignore some bits at the right side.

The AND instruction clears the unneeded bits on the left, or, in other words, leaves only those bits in the EAX register we need.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's load our example into OllyDbg and see, what values are set in EAX/EBX/ECX/EDX after the execution of CPUID:

### Figure 1.109: OllyDbg: After CPUID execution

EAX has **0x000206A7** (my CPU is Intel Xeon E3-1220).
This is `0b00000000000000100000011010100111` in binary form.

Here is how the bits are distributed by fields:

<table>
<thead>
<tr>
<th>field</th>
<th>in binary form</th>
<th>in decimal form</th>
</tr>
</thead>
<tbody>
<tr>
<td>reserved2</td>
<td>0000</td>
<td>0</td>
</tr>
<tr>
<td>extended_family_id</td>
<td>0000000000</td>
<td>0</td>
</tr>
<tr>
<td>extended_model_id</td>
<td>0010</td>
<td>2</td>
</tr>
<tr>
<td>reserved1</td>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>processor_id</td>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>family_id</td>
<td>0110</td>
<td>6</td>
</tr>
<tr>
<td>model</td>
<td>1010</td>
<td>10</td>
</tr>
<tr>
<td>stepping</td>
<td>0111</td>
<td>7</td>
</tr>
</tbody>
</table>

### Listing 1.354: Console output

<table>
<thead>
<tr>
<th>field</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>stepping</td>
<td>7</td>
</tr>
<tr>
<td>model</td>
<td>10</td>
</tr>
<tr>
<td>family_id</td>
<td>6</td>
</tr>
<tr>
<td>processor_type</td>
<td>0</td>
</tr>
<tr>
<td>extended_model_id</td>
<td>2</td>
</tr>
<tr>
<td>extended_family_id</td>
<td>0</td>
</tr>
</tbody>
</table>

### GCC

Let's try GCC 4.4.1 with `-O3` option.

### Listing 1.355: Optimizing GCC 4.4.1

```assembly
main proc near ; DATA XREF: _start+17
push ebp
mov ebp, esp
and esp, 0FFFFFF0h
push esi
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Almost the same. The only thing worth noting is that GCC somehow combines the calculation of `extended_model_id` and `extended_family_id` into one block, instead of calculating them separately before each `printf()` call.

### Handling float data type as a structure

As we already noted in the section about FPU (1.25 on page 220), both float and double types consist of a sign, a significand (or fraction) and an exponent. But will we be able to work with these fields directly? Let’s try this with float.

```
31 30 23 22 0

$ exponent mantissa or fraction
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <memory.h>

struct float_as_struct
{
    unsigned int fraction : 23;  // fractional part
    unsigned int exponent : 8;   // exponent + 0x3FF
    unsigned int sign : 1;       // sign bit
};

float f(float _in)
{
    float f = _in;
    struct float_as_struct t;

    assert (sizeof (struct float_as_struct) == sizeof (float));
    memcpy (&t, &f, sizeof (float));
    t.sign = 1; // set negative sign
    t.exponent = t.exponent + 2; // multiply d by 2^n (n here is 2)
    memcpy (&f, &t, sizeof (float));
    return f;
}

int main()
{
    printf("%f\n", f(1.234));
}
```

The `float_as_struct` structure occupies the same amount of memory as `float`, i.e., 4 bytes or 32 bits.

Now we are setting the negative sign in the input value and also, by adding 2 to the exponent, we thereby multiply the whole number by $2^2$, i.e., by 4.

Let's compile in MSVC 2008 without optimization turned on:

Listing 1.356: Non-optimizing MSVC 2008

```assembly
_t$ = -8 ; size = 4
_f$ = -4 ; size = 4
_in$ = 8 ; size = 4

_f@YAMM@Z PROC ; f
push ebp
    mov ebp, esp
    sub esp, 8

    fld DWORD PTR __in$[ebp]
    fstp DWORD PTR _f$[ebp]
    push 4
    lea eax, DWORD PTR _f$[ebp]
    push eax
    lea ecx, DWORD PTR _t$[ebp]
    push ecx
    call _memcpy
    add esp, 12

    mov edx, DWORD PTR _t$[ebp]
    or edx, -2147483648 ; 80000000H - set minus sign
    mov DWORD PTR _t$[ebp], edx

    mov eax, DWORD PTR _t$[ebp]
    shr eax, 23 ; 00000017H - drop significand
    and eax, 255 ; 000000ffH - leave here only exponent
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
A bit redundant. If it was compiled with /Ox flag there would be no memcpy() call, the f variable is used directly. But it is easier to understand by looking at the unoptimized version.

What would GCC 4.4.1 with -O3 do?

Listing 1.357: Optimizing GCC 4.4.1
The f() function is almost understandable. However, what is interesting is that GCC was able to calculate the result of f(1.234) during compilation despite all this hodge-podge with the structure fields and prepared this argument to printf() as precalculated at compile time!

1.30.7 Exercises

- http://challenges.re/71
- http://challenges.re/72

1.31 The classic struct bug

This is a classic struct bug.

Here is a sample definition:

```c
struct test
{
    int field1;
    int field2;
};
```

And then C files:

```c
void setter(struct test *t, int a, int b)
{
    t->field1=a;
    t->field2=b;
}
```

```c
#include <stdio.h>
void printer(struct test *t)
{
    printf ("%d\n", t->field1);
    printf ("%d\n", t->field2);
}
```

So far so good.

Now you add a third field into the structure, some place between two fields:

```c
struct test
{
    int field1;
    int inserted;
    int field2;
};
```

And you probably modify setter() function, but forget about printer():

```c
void setter(struct test *t, int a, int b, int c)
{
    t->field1=a;
    t->inserted=b;
    t->field2=c;
}
```

You compile your project, but the C file where printer() is residing, isn’t recompiling, because your IDE\textsuperscript{169} or build system has no idea that module depends on a test struct definition. Maybe because #include <new.h> is omitted. Or maybe, new.h header file is included in printer.c via some other

\textsuperscript{169}Integrated development environment
header file. The object file remains untouched (IDE thinks it doesn't need to be recompiled), while setter() function is already a new version. These two object files (old and new) eventually linked into an executable file.

Then you run it, and the setter() sets 3 fields at +0, +4 and +8 offsets. However, the printer() only knows about 2 fields, and gets them from +0 and +4 offsets during printing.

This leads to very obscure and nasty bugs. The reason is that IDE or build system or Makefile doesn’t know the fact that both C files (or modules) depends on the header file with test definition. A popular remedy is to clean everything and recompile.

This is true for C++ classes as well, since they works just like structures: 3.19.1 on page 548.

This is a C/C++’s malady, and a source of criticism, yes. Many newer PLs has better support of modules and interfaces. But keep in mind, when C compiler was created: 1970s, on old PDP computers. So everything was simplified down to this by C creators.

### 1.32 Unions

C/C++ union is mostly used for interpreting a variable (or memory block) of one data type as a variable of another data type.

#### 1.32.1 Pseudo-random number generator example

If we need float random numbers between 0 and 1, the simplest thing is to use a PRNG like the Mersenne twister. It produces random unsigned 32-bit values (in other words, it produces random 32 bits). Then we can transform this value to float and then divide it by RAND_MAX (0xFFFFFFFF in our case)—we getting a value in the 0..1 interval.

But as we know, division is slow. Also, we would like to issue as few FPU operations as possible. Can we get rid of the division?

Let’s recall what a floating point number consists of: sign bit, significand bits and exponent bits. We just have to store random bits in all significand bits to get a random float number!

The exponent cannot be zero (the floating number is denormalized in this case), so we are storing 0b01111111 to exponent—this means that the exponent is 1. Then we filling the significand with random bits, set the sign bit to 0 (which means a positive number) and voilà. The generated numbers is to be between 1 and 2, so we must also subtract 1.

A very simple linear congruential random numbers generator is used in my example\(^{170}\), it produces 32-bit numbers. The PRNG is initialized with the current time in UNIX timestamp format.

Here we represent the float type as an union—it is the C/C++ construction that enables us to interpret a piece of memory as different types. In our case, we are able to create a variable of type union and then access to it as it is float or as it is uint32_t. It can be said, it is just a hack. A dirty one.

The integer PRNG code is the same as we already considered: 1.29 on page 341. So this code in compiled form is omitted.

```c
#include <stdio.h>
#include <stdint.h>
#include <time.h>

// integer PRNG definitions, data and routines:

// constants from the Numerical Recipes book
const uint32_t RNG_a=1664525;
const uint32_t RNG_c=1013904223;
uint32_t RNG_state; // global variable

void my_srand(uint32_t i)
{
    RNG_state=i;
}

\(^{170}\)the idea was taken from: http://go.yurichev.com/17308
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
uint32_t my_rand()
{
    RNG_state=RNG_state*RNG_a+RNG_c;
    return RNG_state;
};

// FPU PRNG definitions and routines:

union uint32_t_float
{
    uint32_t i;
    float f;
};

float float_rand()
{
    union uint32_t_float tmp;
    tmp.i=my_rand() & 0x007fffff | 0x3F800000;
    return tmp.f-1;
};

// test
int main()
{
    my_srand(time(NULL)); // PRNG initialization
    for (int i=0; i<100; i++)
        printf("%f\n", float_rand());
    return 0;
};

x86

Listing 1.358: Optimizing MSVC 2010

SG4238 DB   '?', 0AH, 00H

    fld DWORD PTR tv130[esp+4] ; /
    pop ecx
    ret 0
?float_rand@YAMXZ ENDP
_main PROC
    push esi
    xor eax, eax
    call _time
    push eax
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Function names are so strange here because this example was compiled as C++ and this is name mangling in C++, we will talk about it later: 3.19.1 on page 549. If we compile this in MSVC 2012, it uses the SIMD instructions for the FPU, read more about it here: 1.38.5 on page 443.

**ARM (ARM mode)**

Listing 1.359: Optimizing GCC 4.6.3 (IDA)

```assembly
float_rand
    STMFD SP!, {R3,LR}

```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We'll also make a dump in objdump and we'll see that the FPU instructions have different names than in IDA. Apparently, IDA and binutils developers used different manuals? Perhaps it would be good to know both instruction name variants.

Listing 1.360: Optimizing GCC 4.6.3 (objdump)

```
00000038 <float_rand>:
  38: e92d4008 push   {r3, lr}

  34: e8bd8010 pop   {r4, pc}
  38: 00000000 andeq r0, r0, r0

The instructions at 0x5c in float_rand() and at 0x38 in main() are (pseudo-)random noise.

1.32.2 Calculating machine epsilon

The machine epsilon is the smallest possible value the FPU can work with. The more bits allocated for floating point number, the smaller the machine epsilon. It is $2^{-23} = 1.19\times10^{-07}$ for float and $2^{-52} = 2.22\times10^{-16}$ for double. See also: Wikipedia article.

It's interesting, how easy it's to calculate the machine epsilon:

```c
#include <stdio.h>
#include <stdint.h>

union uint_float
{
    uint32_t i;
    float f;
};

float calculate_machine_epsilon(float start)
{
    union uint_float v;
    v.f=start;
    v.i++;
    return v.f-start;
}

void main()
{
    printf("%g\n", calculate_machine_epsilon(1.0));
}
```

What we do here is just treat the fraction part of the IEEE 754 number as integer and add 1 to it. The resulting floating number is equal to starting_value+machine_epsilon, so we just have to subtract the starting
value (using floating point arithmetic) to measure, what difference one bit reflects in the single precision (float). The union serves here as a way to access IEEE 754 number as a regular integer. Adding 1 to it in fact adds 1 to the fraction part of the number, however, needless to say, overflow is possible, which will add another 1 to the exponent part.

x86

Listing 1.361: Optimizing MSVC 2010

tv130 = 8
_v$ = 8
__start$ = 8
_calculate_machine_epsilon PROC
  fild DWORD PTR __start$[esp-4]
  fst DWORD PTR _v$[esp-4]; this instruction is redundant
  inc DWORD PTR _v$[esp-4]
  fsubr DWORD PTR _v$[esp-4]
  fstd DWORD PTR tv130[esp-4]; \ this instruction pair is also redundant
  fld DWORD PTR tv130[esp-4]; /
  ret 0
_calculate_machine_epsilon ENDP

The second FST instruction is redundant: there is no necessity to store the input value in the same place (the compiler decided to allocate the v variable at the same point in the local stack as the input argument). Then it is incremented with INC, as it is a normal integer variable. Then it is loaded into the FPU as a 32-bit IEEE 754 number, FSUBR does the rest of job and the resulting value is stored in ST0. The last FSTP/FLD instruction pair is redundant, but the compiler didn’t optimize it out.

ARM64

Let’s extend our example to 64-bit:

#include <stdio.h>
#include <stdint.h>

typedef union
{
  uint64_t i;
  double d;
} uint_double;

double calculate_machine_epsilon(double start)
{
  uint_double v;
  v.d=start;
  v.i++;
  return v.d-start;
}

void main()
{
  printf(“%g\n”, calculate_machine_epsilon(1.0));
};

ARM64 has no instruction that can add a number to a FPU D-register, so the input value (that came in D0) is first copied into GPR, incremented, copied to FPU register D1, and then subtraction occurs.

Listing 1.362: Optimizing GCC 4.9 ARM64

calculate_machine_epsilon:
  fmov  x0, d0 ; load input value of double type into X0
  add  x0, x0, 1 ; X0++
  fmov  d1, x0
  fsub  d0, d1, d0 ; subtract
  ret

See also this example compiled for x64 with SIMD instructions: 1.38.4 on page 442.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The new instruction here is MTC1 ("Move To Coprocessor 1"), it just transfers data from GPR to the FPU’s registers.

Listing 1.363: Optimizing GCC 4.4.5 (IDA)

```assembly
calculate_machine_epsilon:
    mfc1 $v0, $f12
    or $at, $zero ; NOP
    addiu $v1, $v0, 1
    mtc1 $v1, $f2
    jr $ra
    sub.s $f0, $f2, $f12 ; branch delay slot
```

Conclusion

It’s hard to say whether someone may need this trickery in real-world code, but as was mentioned many times in this book, this example serves well for explaining the IEEE 754 format and unions in C/C++.

1.32.3 FSACLE instruction replacement

Agner Fog in his *Optimizing subroutines in assembly language / An optimization guide for x86 platforms* work \(^1\) states that FSACLE FPU instruction (calculating \(2^n\)) may be slow on many CPUs, and he offers faster replacement.

Here is my translation of his assembly code to C/C++:

```c
#include <stdint.h>
#include <stdio.h>

union uint_float
{
    uint32_t i;
    float f;
};

float flt_2n(int N)
{
    union uint_float tmp;
    tmp.i=(N<<23)+0x3f800000;
    return tmp.f;
}

struct float_as_struct
{
    unsigned int fraction : 23;
    unsigned int exponent : 8;
    unsigned int sign : 1;
};

float flt_2n_v2(int N)
{
    struct float_as_struct tmp;
    tmp.fraction=0;
    tmp.sign=0;
    tmp.exponent=N+0x7f;
    return *(float*)(&tmp);
}

union uint64_double
{
    uint64_t i;
}
```

\(^1\)http://www.agner.org/optimize/optimizing_assembly.pdf

(For statistics collecting purposes) if you’ve read this far, please click [here](http://www.agner.org/optimize/optimizing_assembly.pdf). Thanks!
double d;
);

double dbl_2n(int N)
{
    union uint64_double tmp;
    tmp.i=((uint64_t)N<<52)+0x3ff0000000000000UL;
    return tmp.d;
};

struct double_as_struct
{
    uint64_t fraction: 52;
    int exponent: 11;
    int sign: 1;
};

double dbl_2n_v2(int N)
{
    struct double_as_struct tmp;
    tmp.fraction=0;
    tmp.sign=0;
    tmp.exponent=N+0x3ff;
    return *(double*)(&tmp);
};

int main()
{
    // 2^11 = 2048
    printf(“%f\n”, flt_2n(11));
    printf(“%f\n”, flt_2n_v2(11));
    printf(“%lf\n”, dbl_2n(11));
    printf(“%lf\n”, dbl_2n_v2(11));
};

FScale instruction may be faster in your environment, but still, it’s a good example of union’s and the fact that exponent is stored in \(2^n\) form, so an input \(n\) value is shifted to the exponent in IEEE 754 encoded number. Then exponent is then corrected with addition of 0x3f800000 or 0x3ff0000000000000.
The same can be done without shift using struct, but internally, shift operations still occurred.

### 1.32.4 Fast square root calculation

Another well-known algorithm where float is interpreted as integer is fast calculation of square root.

Listing 1.364: The source code is taken from Wikipedia: [http://go.yurichev.com/17364](http://go.yurichev.com/17364)

```c
/* Assumes that float is in the IEEE 754 single precision floating point format
* and that int is 32 bits. */
float sqrt_approx(float z)
{
    int val_int = *(int*)&z; /* Same bits, but as an int */
    /* To justify the following code, prove that */
    /* (((val_int / 2^m) - b) / 2) + b) * 2^m = ((val_int - 2^m) / 2) + ((b + 1) / 2) * 2^m */
    /* where */
    /* b = exponent bias */
    /* m = number of mantissa bits */
    /* */
    val_int -= 1 << 23; /* Subtract 2^m. */
    val_int >>= 1; /* Divide by 2. */
```

(For statistics collecting purposes) if you’ve read this far, please click [here](http://go.yurichev.com/17364). Thanks!
val_int += 1 << 29; /* Add ((b + 1) / 2) * 2^m. */
return *(float*)&val_int; /* Interpret again as float */
}

As an exercise, you can try to compile this function and to understand, how it works.

There is also well-known algorithm of fast calculation of $\frac{1}{\sqrt{x}}$. Algorithm became popular, supposedly, because it was used in Quake III Arena.

Algorithm description can be found in Wikipedia: [http://go.yurichev.com/17360](http://go.yurichev.com/17360).

### 1.33 Pointers to functions

A pointer to a function, as any other pointer, is just the address of the function's start in its code segment. They are often used for calling callback functions\(^{172}\).

Well-known examples are:
- qsort()\(^{173}\), atexit()\(^{174}\) from the standard C library;
- *NIX OS signals\(^{175}\);
- thread starting: CreateThread() (win32), pthread_create() (POSIX);
- lots of win32 functions, like EnumChildWindows()\(^{176}\).
- lots of places in the Linux kernel, for example the filesystem driver functions are called via callbacks: [http://go.yurichev.com/17076](http://go.yurichev.com/17076)
- The GCC plugin functions are also called via callbacks: [http://go.yurichev.com/17077](http://go.yurichev.com/17077)

So, the qsort() function is an implementation of quicksort in the C/C++ standard library. The function is able to sort anything, any type of data, as long as you have a function to compare these two elements and qsort() is able to call it.

The comparison function can be defined as:

```c
int (*compare)(const void *, const void *)
```

Let's use the following example:

```c
/* ex3 Sorting ints with qsort */
#include <stdio.h>
#include <stdlib.h>

int comp(const void * _a, const void * _b)
{
    const int *a=(const int *)_a;
    const int *b=(const int *)_b;
    if (*a==*b)
        return 0;
    else
        if (*a < *b)
            return -1;
        else
            return 1;
}

int main(int argc, char* argv[])
{
    int numbers[10]={(1892,45,200,-98,4087,5,-12345,1087,88,-100000);
```

\(^{172}\)wikipedia\(^{173}\)wikipedia\(^{174}\)http://go.yurichev.com/17073\(^{175}\)wikipedia\(^{176}\)MSDN

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
1.33.1 MSVC

Let’s compile it in MSVC 2010 (some parts were omitted for the sake of brevity) with `/Ox` option:

```
int i;

/* Sort the array */
qsort(numbers,10,sizeof(int),comp);
for (i=0;i<9;i++)
    printf("Number = %d\n",numbers[i]);
return 0;
```

Listing 1.365: Optimizing MSVC 2010: /GS- /MD

```
_a$ = 8 ; size = 4
__b$ = 12 ; size = 4
__comp PROC
    mov    eax, DWORD PTR __a$[esp-4]
    mov    ecx, DWORD PTR __b$[esp-4]
    mov    eax, DWORD PTR [eax]
    mov    ecx, DWORD PTR [ecx]
    cmp    eax, ecx
    jne    SHORT $LN4@comp
    xor    eax, eax
    ret    0
$LN4@comp:
    xor    edx, edx
    cmp    eax, ecx
    setge  dl
    lea    eax, DWORD PTR [edx+edx-1]
    ret    0
__comp ENDP

,numbers$ = -40 ; size = 40
_argc$ = 8 ; size = 4
.argv$ = 12 ; size = 4
_main PROC
    sub    esp, 40 ; 00000020H
    push   esi
    push   OFFSET __comp
    push   4
    lea    eax, DWORD PTR _numbers$[esp+52]
    push   10 ; 000000aH
    push   eax
    mov    DWORD PTR _numbers$[esp+60], 1892 ; 00000764H
    mov    DWORD PTR _numbers$[esp+64], 45 ; 0000002dH
    mov    DWORD PTR _numbers$[esp+68], 200 ; 000000c8H
    mov    DWORD PTR _numbers$[esp+72], -98 ; fffff9eH
    mov    DWORD PTR _numbers$[esp+76], 4087 ; 00000ff7H
    mov    DWORD PTR _numbers$[esp+80], 5
    mov    DWORD PTR _numbers$[esp+84], -12345 ; ffffc7fH
    mov    DWORD PTR _numbers$[esp+88], 1087 ; 0000043fH
    mov    DWORD PTR _numbers$[esp+92], 88 ; 00000058H
    mov    DWORD PTR _numbers$[esp+96], -100000 ; fffe7960H
    call   _qsort
    add    esp, 16 ; 00000010H
...
```

Nothing surprising so far. As a fourth argument, the address of label __comp is passed, which is just a place where comp() is located, or, in other words, the address of the very first instruction of that function.

How does qsort() call it?

Let’s take a look at this function, located in MSVCR80.DLL (a MSVC DLL module with C standard library functions):

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!

comp—is the fourth function argument. Here the control gets passed to the address in the comp argument. Before it, two arguments are prepared for comp(). Its result is checked after its execution.

That’s why it is dangerous to use pointers to functions. First of all, if you call qsort() with an incorrect function pointer, qsort() may pass control flow to an incorrect point, the process may crash and this bug will be hard to find.

The second reason is that the callback function types must comply strictly, calling the wrong function with wrong arguments of wrong types may lead to serious problems, however, the crashing of the process is not a problem here —the problem is how to determine the reason for the crash —because the compiler may be silent about the potential problems while compiling.
Let’s load our example into OllyDbg and set a breakpoint on `comp()` . We can see how the values are compared at the first `comp()` call:

OllyDbg shows the compared values in the window under the code window, for convenience. We can also see that the SP points to RA, where the `qsort()` function is (located in MSVCR100.DLL).

![OllyDbg screenshot](image)

Figure 1.110: OllyDbg: first call of `comp()`

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
By tracing (F8) until the RETN instruction and pressing F8 one more time, we return to the qsort() function:

That has been a call to the comparison function.
Here is also a screenshot of the moment of the second call of comp()—now values that have to be compared are different:

![Figure 1.112: OllyDbg: second call of comp()](image)

**MSVC + tracer**

Let's also see which pairs are compared. These 10 numbers are being sorted: 1892, 45, 200, -98, 4087, 5, -12345, 1087, 88, -100000.

We got the address of the first CMP instruction in comp(), it is 0x0040100C and we've set a breakpoint on it:

```
tracer.exe -l:17_1.exe bpx=17_1.exe!0x0040100C
```

Now we get some information about the registers at the breakpoint:

```
PID=4336|New process 17_1.exe
(0) 17_1.exe!0x40100c
EAX=0x00000005 EBX=0x0051f7c8 ECX=0x00000005 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=IF
(0) 17_1.exe!0x40100c
EAX=0x00000005 EBX=0x0051f7c8 ECX=0xfffe7960 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=PF ZF IF
(0) 17_1.exe!0x40100c
EAX=0x00000005 EBX=0x0051f7c8 ECX=0x00000005 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=CF PF ZF IF
...```

Let's filter out EAX and ECX and we got:

```
EAX=0x00000764 ECX=0x00000005
EAX=0x00000005 ECX=0xfffe7960
EAX=0x00000764 ECX=0x00000005
EAX=0x0000002d ECX=0x00000005
EAX=0x0000058 ECX=0x00000005
EAX=0x0000043f ECX=0x00000005
EAX=0xffffffff ECX=0x00000005
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
That's 34 pairs. Therefore, the quick sort algorithm needs 34 comparison operations to sort these 10 numbers.
MSVC + tracer (code coverage)

We can also use the tracer’s feature to collect all possible register values and show them in IDA. Let’s trace all instructions in comp():

```
ismer.exe -l:17_1.exe bpf=17_1.exe!0x0401000,trace:cc
```

We get an .idc-script for loading into IDA and load it:

[Code snippet]

Figure 1.113: tracer and IDA. N.B.: some values are cut at right

IDA gave the function a name (PtFuncCompare)—because IDA sees that the pointer to this function is passed to qsort().

We see that the a and b pointers are pointing to various places in the array, but the step between them is 4, as 32-bit values are stored in the array.

We see that the instructions at 0x401010 and 0x401012 were never executed (so they left as white): indeed, comp() has never returned 0, because there no equal elements in the array.

### 1.33.2 GCC

Not a big difference:

```
lea     eax, [esp+40h+var_28]
mov     [esp+40h+var_40], eax
mov     [esp+40h+var_28], 764h
mov     [esp+40h+var_24], 20h
mov     [esp+40h+var_20], 0C8h
mov     [esp+40h+var_1C], 0FFFFFF9Eh
mov     [esp+40h+var_18], 0FF7h
mov     [esp+40h+var_14], 5
mov     [esp+40h+var_10], 0FFFFCFC7h
mov     [esp+40h+var_C], 43Fh
mov     [esp+40h+var_8], 58h
mov     [esp+40h+var_4], 0FFE7960h
mov     [esp+40h+var_34], offset comp
mov     [esp+40h+var_38], 4
mov     [esp+40h+var_3C], 0Ah
call    _qsort
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
comp() function:

```
public comp
comp proc near
arg_0 = dword ptr 8
arg_4 = dword ptr 0Ch

push ebp
mov ebp, esp
mov eax, [ebp+arg_4]
mov ecx, [ebp+arg_0]
mov edx, [eax]
xor eax, eax
cmp [ecx], edx
jnz short loc_8048458
pop ebp
retn

loc_8048458:
    setnl al
    movzx eax, al
    lea eax, [eax+eax-1]
    pop ebp
    retn
comp endp
```

The implementation of qsort() is located in libc.so.6 and it is in fact just a wrapper for qsort_r(). In turn, it is calling quicksort(), where our defined function is called via a passed pointer:

Listing 1.368: (file libc.so.6, glibc version—2.10.1)

```
... .text:0002DDF6 mov edx, [ebp+arg_10]
    .text:0002DDF9 mov [esp+4], esi
    .text:0002DDFD mov [esp], edi
    .text:0002DE00 mov [esp+8], edx
    .text:0002DE04 call [ebp+arg_C]
... 
```

**GCC + GDB (with source code)**

Obviously, we have the C-source code of our example (1.33 on page 387), so we can set a breakpoint (b) on line number 11—the line where the first comparison occurs. We also have to compile the example with debugging information included (-g), so the table with addresses and corresponding line numbers is present.

We can also print values using variable names (p): the debugging information also has tells us which register and/or local stack element contains which variable.

We can also see the stack (bt) and find out that there is some intermediate function msort_with_tmp() used in Glibc.

Listing 1.369: GDB session

```
dennis@ubuntuvm:~/polygon$ gcc 17_1.c -g
dennis@ubuntuvm:~/polygon$ gdb ./a.out
GNU gdb (GDB) 7.6.1-ubuntu
Copyright (C) 2013 Free Software Foundation, Inc.
... Reading symbols from /home/dennis/polygon/a.out...done.
(gdb) b 17_1.c:11
Breakpoint 1 at 0x804845f: file 17_1.c, line 11.

11 if (*a==*b)
```

177 A concept like thunk function

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
GCC + GDB (no source code)

But often there is no source code at all, so we can disassemble the `comp()` function (disas), find the very first CMP instruction and set a breakpoint (`b`) at that address.

At each breakpoint, we are going to dump all register contents (info registers). The stack information is also available (bt), but partially: there is no line number information for `comp()`.

Listing 1.370: GDB session

dennis@ubuntuvm:/~polygon$ gcc 17_1.c

1.33.3 Danger of pointers to functions

As we can see, `qsort()` function expects a pointer to function which takes two `void*` arguments and returning integer. If you have several comparison functions in your code (one compares string, another—integers, etc), it’s very easy to mix them up with each other. You could try to sort array of string using function which compares integers, and compiler will not warn you about bug.

1.34 64-bit values in 32-bit environment

In a 32-bit environment, GPR’s are 32-bit, so 64-bit values are stored and passed as 32-bit value pairs.\(^\text{178}\)

1.34.1 Returning of 64-bit value

```c
#include <stdint.h>

uint64_t f ()
{
    return 0x1234567890ABCDEF;
}
```

x86

In a 32-bit environment, 64-bit values are returned from functions in the EDX:EAX register pair.

Listing 1.371: Optimizing MSVC 2010

```
_f PROC
    mov    eax, -1867788817 ; 90abcdefH
    mov    edx, 305419896 ; 12345678H
    ret
_f ENDP
```

ARM

A 64-bit value is returned in the R0-R1 register pair (R1 is for the high part and R0 for the low part):

\(^\text{178}\)By the way, 32-bit values are passed as pairs in 16-bit environment in the same way: 3.31.4 on page 651

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Listing 1.372: Optimizing Keil 6/2013 (ARM mode)

```
||f|| PROC
  LDR  r0, |Lo.12|
  LDR  r1, |Lo.16|
  BX   lr
ENDP
|Lo.12| DCD  0x90abcdef
|Lo.16| DCD  0x12345678
```

MIPS

A 64-bit value is returned in the V0-V1 ($2-$3) register pair (V0 ($2) is for the high part and V1 ($3) for the low part):

Listing 1.373: Optimizing GCC 4.4.5 (assembly listing)

```
li $3, -1867841536  # 0xffffffff90ab0000
li $2, 305397760    # 0x12340000
ori $3, $3, 0xcdef
j $31               
ori $2, $2, 0x5678
```

Listing 1.374: Optimizing GCC 4.4.5 (IDA)

```
lui $v1, 0x90AB
lui $v0, 0x1234
li $v1, 0x90ABCDEF
jr $ra
li $v0, 0x12345678
```

1.34.2 Arguments passing, addition, subtraction

```c
#include <stdint.h>

uint64_t f_add (uint64_t a, uint64_t b)
{
    return a+b;
};

void f_add_test ()
{
#ifdef __GNUC__
    printf("%lld\n", f_add(12345678901234, 23456789012345));
#else
    printf("%I64d\n", f_add(12345678901234, 23456789012345));
#endif
};

uint64_t f_sub (uint64_t a, uint64_t b)
{
    return a-b;
};
```

x86

Listing 1.375: Optimizing MSVC 2012 /Ob1

```
a$ = 8 ; size = 8
b$ = 16; size = 8
f_add PROC
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We can see in the \texttt{f_add_test()} function that each 64-bit value is passed using two 32-bit values, high part first, then low part. Addition and subtraction occur in pairs as well.

In addition, the low 32-bit part are added first. If carry has been occurred while adding, the CF flag is set.

The following ADC instruction adds the high parts of the values, and also adds 1 if $CF = 1$.

Subtraction also occurs in pairs. The first \texttt{SUB} may also turn on the CF flag, which is to be checked in the subsequent SBB instruction: if the carry flag is on, then 1 is also to be subtracted from the result.

It is easy to see how the \texttt{f_add()} function result is then passed to \texttt{printf()}. 

\textbf{Listing 1.376: GCC 4.8.1 -O1 -fno-inline}

\begin{verbatim}
_f_add:   mov   eax, DWORD PTR _a$[esp-4]
         add   eax, DWORD PTR _b$[esp-4]
         mov   edx, DWORD PTR _a$[esp]
         adc   edx, DWORD PTR _b$[esp]
         ret   0

_f_add_test PROC
    push  5461   ; 00001555H
    push  1972608889 ; 75939f79H
    push  2874    ; 00000b3aH
    push  1942892530 ; 73ce2ff2H
    call   _f_add
    push   edx
    push   eax
    push   OFFSET $SG1436 ; '%I64d', 0aH, 00H
    call   _printf
    add    esp, 28
    ret    0

_f_add_test ENDP

_f_sub PROC
    mov   eax, DWORD PTR _a$[esp-4]
    sub   eax, DWORD PTR _b$[esp-4]
    mov   edx, DWORD PTR _a$[esp]
    sbb   edx, DWORD PTR _b$[esp]
    ret   0

_f_sub ENDP
\end{verbatim}
ARM

Listing 1.377: Optimizing Keil 6/2013 (ARM mode)

f_add PROC
  ADDS r0, r0, r2
  ADC r1, r1, r3
  BX lr
ENDP

f_sub PROC
  SUBS r0, r0, r2
  SBC r1, r1, r3
  BX lr
ENDP

f_add_test PROC
  PUSH {r4, lr}
  LDR r2, |L0.68| ; 0x75939f79
  LDR r3, |L0.72| ; 0x00001555
  LDR r0, |L0.76| ; 0x73ce2ff2
  LDR r1, |L0.80| ; 0x00000b3a
  BL f_add
  POP {r4, lr}
  MOV r2, r0
  MOV r3, r1
  ADR r0, |L0.84| ; "%I64d\n"
  B __2printf
ENDP

|L0.68|
DCD 0x75939f79
|L0.72|
DCD 0x00001555
|L0.76|
DCD 0x73ce2ff2
|L0.80|
DCD 0x00000b3a
|L0.84|
DCB "%I64d\n", 0

The first 64-bit value is passed in R0 and R1 register pair, the second in R2 and R3 register pair. ARM has the ADC instruction as well (which counts carry flag) and SBC (“subtract with carry”). Important thing: when the low parts are added/subtracted, ADDS and SUBS instructions with -S suffix are used. The -S suffix stands for “set flags”, and flags (esp. carry flag) is what consequent ADC/SBC instructions definitely need. Otherwise, instructions without the -S suffix would do the job (ADD and SUB).

MIPS

Listing 1.378: Optimizing GCC 4.4.5 (IDA)

f_add:
  ; $a0 - high part of a
  ; $a1 - low part of a
  ; $a2 - high part of b
  ; $a3 - low part of b
    addu $v1, $a3, $a1 ; sum up low parts
    addu $a0, $a2, $a0 ; sum up high parts
  ; will carry generated while summing up low parts?
    sltu $v0, $v1, $a3
    jr $ra
  ; add 1 to high part of result if carry should be generated:
    addu $v0, $a0 ; branch delay slot
  ; $v0 - high part of result

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
MIPS has no flags register, so there is no such information present after the execution of arithmetic operations. So there are no instructions like x86's ADC and SBB. To know if the carry flag would be set, a comparison (using SLTU instruction) also occurs, which sets the destination register to 1 or 0. This 1 or 0 is then added or subtracted to/from the final result.

### 1.34.3 Multiplication, division

```c
#include <stdint.h>

uint64_t f_mul (uint64_t a, uint64_t b) {
    return a*b;
};

uint64_t f_div (uint64_t a, uint64_t b) {
    return a/b;
};

uint64_t f_rem (uint64_t a, uint64_t b) {
```

<table>
<thead>
<tr>
<th>ASCII</th>
</tr>
</thead>
<tbody>
<tr>
<td>402</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
x86

Listing 1.379: Optimizing MSVC 2013 /Ob1

```
a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_mul PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _b$[ebp+4]
    push eax
    mov ecx, DWORD PTR _b$[ebp]
    push ecx
    mov edx, DWORD PTR _a$[ebp+4]
    push edx
    mov eax, DWORD PTR _a$[ebp]
    push eax
    call __allmul ; long long multiplication
    pop ebp
    ret 0
_f_mul ENDP

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_div PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _b$[ebp+4]
    push eax
    mov ecx, DWORD PTR _b$[ebp]
    push ecx
    mov edx, DWORD PTR _a$[ebp+4]
    push edx
    mov eax, DWORD PTR _a$[ebp]
    push eax
    call __aulldiv ; unsigned long long division
    pop ebp
    ret 0
_f_div ENDP

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_rem PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _b$[ebp+4]
    push eax
    mov ecx, DWORD PTR _b$[ebp]
    push ecx
    mov edx, DWORD PTR _a$[ebp+4]
    push edx
    mov eax, DWORD PTR _a$[ebp]
    push eax
    call __aullrem ; unsigned long long remainder
    pop ebp
    ret 0
_f_rem ENDP
```

Multiplication and division are more complex operations, so usually the compiler embeds calls to a library functions doing that.

These functions are described here: .5 on page 1016.

Listing 1.380: Optimizing GCC 4.8.1 -fno-inline

```
f_mul:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
GCC does the expected, but the multiplication code is inlined right in the function, thinking it could be more efficient. GCC has different library function names: .4 on page 1016.

**ARM**

Keil for Thumb mode inserts library subroutine calls:

```
|__f_mul__| PROC
PUSH    {r4,lr}
BL    __aeabi_lmul
POP    {r4,pc}
ENDP

|__f_div__| PROC
PUSH    {r4,lr}
BL    __aeabi_uldivmod
POP    {r4,pc}
ENDP

|__f_rem__| PROC
PUSH    {r4,lr}
BL    __aeabi_uldivmod
MOVS    r0,r2
MOVS    r1,r3
POP    {r4,pc}
ENDP

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Keil for ARM mode, on the other hand, is able to produce 64-bit multiplication code:

Listing 1.382: Optimizing Keil 6/2013 (ARM mode)

```assembly
||f_mul|| PROC
| PUSH   {r4,lr}
| UMULL r12,r4,r0,r2
| MLA   r1,r2,r1,r4
| MLA   r1,r0,r3,r1
| MOV   r0,r12
| POP   {r4,pc}
| ENDP

||f_div|| PROC
| PUSH   {r4,lr}
| BL     __aeabi_uldivmod
| POP   {r4,pc}
| ENDP

||f_rem|| PROC
| PUSH   {r4,lr}
| BL     __aeabi_uldivmod
| MOV   r0,r2
| MOV   r1,r3
| POP   {r4,pc}
| ENDP

MIPS

Optimizing GCC for MIPS can generate 64-bit multiplication code, but has to call a library routine for 64-bit division:

Listing 1.383: Optimizing GCC 4.4.5 (IDA)

```assembly
f_mul:
  mult  $a2, $a1
  mflo  $v0
  or    $at, $zero ; NOP
  or    $at, $zero ; NOP
  mult  $a0, $a3
  mflo  $a0
  addu  $v0, $a0
  or    $at, $zero ; NOP
  multi $a3, $a1
  mfhi  $a2
  mflo  $v1
  jr    $ra
  addu  $v0, $a2

f_div:
  var_10 = -0x10
  var_4  = -4
  lui   $gp, (__gnu_local_gp >> 16)
  addiu $sp, -0x20
  la    $gp, (__gnu_local_gp & 0xFFFF)
  sw    $ra, 0x20+var_4($sp)
  sw    $gp, 0x20+var_10($sp)
  lw    $t9, (__udivdi3 & 0xFFFF)($gp)
  or    $at, $zero
  jalr  $t9
  or    $at, $zero
  lw    $ra, 0x20+var_4($sp)
  or    $at, $zero
  jr    $ra
  addiu $sp, 0x20

f_rem:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
406

\[ \text{var}_{10} = -0x10 \]
\[ \text{var}_4 = -4 \]

\begin{verbatim}
lui $gp, \_gnu_local_gp >> 16
addiu $sp, -0x20
la $gp, \_gnu_local_gp & 0xFFFF
sw $ra, 0x20+var_4($sp)
sw $gp, 0x20+var_{10}($sp)
lw $t9, \_umoddi3 & 0xFFFF($gp)
or $at, $zero
jalr $t9
or $at, $zero
lw $ra, 0x20+var_4($sp)
or $at, $zero
jr $ra
addiu $sp, 0x20
\end{verbatim}

There are a lot of NOPs, probably delay slots filled after the multiplication instruction (it's slower than other instructions, after all).

### 1.34.4 Shifting right

```c
#include <stdint.h>

uint64_t f (uint64_t a)
{
    return a>>7;
};
```

\section*{x86}

\begin{listing}
\begin{verbatim}
a$ = 8 ; size = 8
_f PROC
    mov eax, DWORD PTR a$[esp-4]
    mov edx, DWORD PTR _a$[esp]
    shrd eax, edx, 7
    shr edx, 7
    ret 0
_f ENDP
\end{verbatim}
\caption{Optimizing MSVC 2012 /Ob1}
\end{listing}

\begin{listing}
\begin{verbatim}
f:
    mov edx, DWORD PTR [esp+8]
    mov eax, DWORD PTR [esp+4]
    shrd eax, edx, 7
    shr edx, 7
    ret
\end{verbatim}
\caption{Optimizing GCC 4.8.1 -fno-inline}
\end{listing}

Shifting also occurs in two passes: first the lower part is shifted, then the higher part. But the lower part is shifted with the help of the SHRD instruction, it shifts the value of EAX by 7 bits, but pulls new bits from EDX, i.e., from the higher part. In other words, 64-bit value from EDX:EAX register’s pair, as a whole, is shifted by 7 bits and lowest 32 bits of result are placed into EAX. The higher part is shifted using the much more popular SHR instruction: indeed, the freed bits in the higher part must be filled with zeros.

\section*{ARM}

ARM doesn’t have such instruction as SHRD in x86, so the Keil compiler ought to do this using simple shifts and OR operations:

\begin{verbatim}
    shrd eax, edx, 7
    shr edx, 7
    ret
\end{verbatim}

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
### MIPS

GCC for MIPS follows the same algorithm as Keil does for Thumb mode:

```c
f:
    sll $v0, $a0, 25
    srl $v1, $a1, 7
    or $v1, $v0, $v1
    jr $ra
    srl $v0, $a0, 7
```

### 1.34.5 Converting 32-bit value into 64-bit one

```c
#include <stdint.h>

int64_t f (int32_t a)
{
    return a;
};
```

### x86

Here we also run into necessity to extend a 32-bit signed value into a 64-bit signed one. Unsigned values are converted straightforwardly: all bits in the higher part must be set to 0. But this is not appropriate for signed data types: the sign has to be copied into the higher part of the resulting number.

The CDQ instruction does that here, it takes its input value in EAX, extends it to 64-bit and leaves it in the EDX:EAX register pair. In other words, CDQ gets the number sign from EAX (by getting the most significant bit in EAX), and depending of it, sets all 32 bits in EDX to 0 or 1. Its operation is somewhat similar to the MOVVSX instruction.
Keil for ARM is different: it just arithmetically shifts right the input value by 31 bits. As we know, the sign bit is MSB, and the arithmetical shift copies the sign bit into the “emerged” bits. So after “ASR r1,r0,#31”, R1 containing 0xFFFFFFFF if the input value has been negative and 0 otherwise. R1 contains the high part of the resulting 64-bit value. In other words, this code just copies the MSB (sign bit) from the input value in R0 to all bits of the high 32-bit part of the resulting 64-bit value.

MIPS

GCC for MIPS does the same as Keil did for ARM mode:

```
Listing 1.391: Optimizing GCC 4.4.5 (IDA)
f:
sra $v0, $a0, 31
jr $ra
move $v1, $a0
```

1.35 LARGE_INTEGER structure case

Imagine this: late 1980s, you’re Microsoft, and you’re developing a new serious OS (Windows NT), that will compete with Unices. Target platforms has both 32-bit and 64-bit CPUs. And you need a 64-bit integer datatype for all sort of purposes, starting at FILETIME179 structure.

The problem: not all target C/C++ compilers support 64-bit integer yet (this is late 1980s). Surely, this will be changed in (near) future, but not now. What would you do?

While reading this, try to stop (and/or close this book) and think, how can you solve this problem.

179https://docs.microsoft.com/en-us/windows/desktop/api/minwinbase/ns-minwinbase-filetime

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This is what Microsoft did, something like this\textsuperscript{180}:

```
union U_LARGE_INTEGER
{
    struct backward_compatibility
    {
        DWORD LowPart;
        DWORD HighPart;
    };
    #ifdef NEW_FANCY_COMPILER_SUPPORTING_64_BIT
    ULONGLONG QuadPart;
    #endif
};
```

This is a chunk of 8 bytes, which can be accessed via 64-bit integer QuadPart (if compiled using newer compiler), or using two 32-bit integers (if compiled using old one).

QuadPart field is just absent here when compiled using old compiler.

Order is crucial: first field (LowPart) maps to lower 4 bytes of 64-bit value, second field (HighPart) maps to higher 4 bytes.

Microsoft also added utility functions for all the arithmetical operation, in a same manner as I already described: \textit{1.34 on page 398}.

And this is from the leaked Windows 2000 source code base:

```
Listing 1.392: i386 arch

```++
;
; LARGE_INTEGER
; RtlLargeIntegerAdd (;
; IN LARGE_INTEGER Addend1,;
; IN LARGE_INTEGER Addend2
;
);
; Routine Description:
;
; This function adds a signed large integer to a signed large integer and
; returns the signed large integer result.
;
; Arguments:
;
; (TOS+4) = Addend1 - first addend value
; (TOS+12) = Addend2 - second addend value
;
; Return Value:
;
; The large integer result is stored in (edx:eax)
;
;--

  cPublicProc _RtlLargeIntegerAdd ,4
  cPublicFpo 4,0

    mov  eax,[esp]+4 ; (eax)=add1.low
    add  eax,[esp]+12 ; (eax)=sum.low
    mov  edx,[esp]+8 ; (edx)=add1.hi
    adc  edx,[esp]+16 ; (edx)=sum.hi
    stdRET _RtlLargeIntegerAdd

stdENDP _RtlLargeIntegerAdd
```

```
Listing 1.393: MIPS arch

```

```

\textit{180}Not a copypasted source code, I wrote this

(For statistics collecting purposes) if you’ve read this far, please click \textcolor{blue}{here}. Thanks!
addu t0,t0,a2 // add low parts of large integer
addu t1,t1,a3 // add high parts of large integer
sltu t2,t0,a2 // generate carry from low part
addu t1,t1,t2 // add carry to high part
sw t0,0(a0) // store low part of result
sw t1,4(a0) // store high part of result
move v0,a0 // set function return register
j ra // return
.end RtlLargeIntegerAdd

Now two 64-bit architectures:

Listing 1.394: Itanium arch

```
LEAF_ENTRY(RtlLargeIntegerAdd)
add v0 = a0, a1 // add both quadword arguments
LEAF_RETURN

LEAF_EXIT(RtlLargeIntegerAdd)
```

Listing 1.395: DEC Alpha arch

```
LEAF_ENTRY(RtlLargeIntegerAdd)
addq a0, a1, v0 // add both quadword arguments
ret zero, (ra) // return

.end RtlLargeIntegerAdd
```

No need using 32-bit instructions on Itanium and DEC Alpha—64-bit ones are here already.

And this is what we can find in Windows Research Kernel:

```
DECLSPEC_DEPRECATED_DDK
// Use native __int64 math
inline
LARGE_INTEGER
NTAPI
RtlLargeIntegerAdd ( 
    LARGE_INTEGER Addend1,
    LARGE_INTEGER Addend2
)
{
    LARGE_INTEGER Sum;
    return Sum;
}
```

All these functions can be dropped (in future), but now they just operate on QuadPart field. If this piece
of code is to be compiled using a modern 32-bit compiler (that supports 64-bit integer), it will generate
two 32-bit additions under the hood. From this moment, LowPart/HighPart fields can be dropped from the
LARGE_INTEGER union/structure.

Would you use such a technique today? Probably not, but if someone would need 128-bit integer data
type, you can implement it just like this.

Also, needless to say, this works thanks to little-endian (2.8 on page 469) (all architectures Windows NT
was developed for are little-endian). This trick wouldn’t be possible on a big-endian architecture.

### 1.36 SIMD

SIMD is an acronym: Single Instruction, Multiple Data.

As its name implies, it processes multiple data using only one instruction.

Like the FPU, that CPU subsystem looks like a separate processor inside x86.
SIMD began as MMX in x86. 8 new 64-bit registers appeared: MM0-MM7.

Each MMX register can hold 2 32-bit values, 4 16-bit values or 8 bytes. For example, it is possible to add 8 8-bit values (bytes) simultaneously by adding two values in MMX registers.

One simple example is a graphics editor that represents an image as a two dimensional array. When the user changes the brightness of the image, the editor must add or subtract a coefficient to/from each pixel value. For the sake of brevity if we say that the image is grayscale and each pixel is defined by one 8-bit byte, then it is possible to change the brightness of 8 pixels simultaneously.

By the way, this is the reason why the saturation instructions are present in SIMD.

When the user changes the brightness in the graphics editor, overflow and underflow are not desirable, so there are addition instructions in SIMD which are not adding anything if the maximum value is reached, etc.

When MMX appeared, these registers were actually located in the FPU’s registers. It was possible to use either FPU or MMX at the same time. One might think that Intel saved on transistors, but in fact the reason of such symbiosis was simpler —older OSes that are not aware of the additional CPU registers would not save them at the context switch, but saving the FPU registers. Thus, MMX-enabled CPU + old OS + process utilizing MMX features will still work.

SSE—is extension of the SIMD registers to 128 bits, now separate from the FPU.

AVX—another extension, to 256 bits.

Now about practical usage.

Of course, this is memory copy routines (memcpy), memory comparing (memcmp) and so on.

One more example: the DES encryption algorithm takes a 64-bit block and a 56-bit key, encrypt the block and produces a 64-bit result. The DES algorithm may be considered as a very large electronic circuit, with wires and AND/OR/NOT gates.

Bitslice DES is the idea of processing groups of blocks and keys simultaneously. Let’s say, variable of type unsigned int on x86 can hold up to 32 bits, so it is possible to store there intermediate results for 32 block-key pairs simultaneously, using 64+56 variables of type unsigned int.

There is an utility to brute-force Oracle RDBMS passwords/hashes (ones based on DES), using slightly modified bitslice DES algorithm for SSE2 and AVX—now it is possible to encrypt 128 or 256 block-keys pairs simultaneously.

http://go.yurichev.com/17313

1.36.1 Vectorization

Vectorization is when, for example, you have a loop taking couple of arrays for input and producing one array. The loop body takes values from the input arrays, does something and puts the result into the output array. Vectorization is to process several elements simultaneously.

Vectorization is not very fresh technology: the author of this textbook saw it at least on the Cray Y-MP supercomputer line from 1988 when he played with its “lite” version Cray Y-MP EL.

For example:

```c
for (i = 0; i < 1024; i++)
{
    C[i] = A[i]*B[i];
}
```

This fragment of code takes elements from A and B, multiplies them and saves the result into C.

If each array element we have is 32-bit int, then it is possible to load 4 elements from A into a 128-bit XMM-register, from B to another XMM-registers, and by executing PMULLD (Multiply Packed Signed Dword Integers and Store Low Result) and PMULHW (Multiply Packed Signed Integers and Store High Result), it is possible to get 4 64-bit products at once.

Thus, loop body execution count is 1024/4 instead of 1024, that is 4 times less and, of course, faster.

181 http://go.yurichev.com/17329
182 Wikipedia: vectorization
183 Remotely. It is installed in the museum of supercomputers: http://go.yurichev.com/17081

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Addition example

Some compilers can do vectorization automatically in simple cases, e.g., Intel C++\textsuperscript{184}.

Here is tiny function:

```c
int f (int sz, int *ar1, int *ar2, int *ar3)
{
    for (int i=0; i<sz; i++)
        ar3[i]=ar1[i]+ar2[i];
    return 0;
}
```

Intel C++

Let's compile it with Intel C++ 11.1.051 win32:

```
icl intel.cpp /QaxSSE2 /Faintel.asm /Ox
```

We got (in IDA):

```c
; int __cdecl f(int, int *, int *, int *)
  public ?f@YAHPPAH0@Z proc near
var_10 = dword ptr -10h
sz   = dword ptr  4
ar1  = dword ptr  8
ar2  = dword ptr  0Ch
ar3  = dword ptr  10h

    push    edi
    push    esi
    push    ebx
    push    esi
    mov     edx, [esp+10h+sz]
    test    edx, edx
    jle     loc_15B
    mov     eax, [esp+10h+ar3]
    cmp      edx, 6
defl    loc_143
    cmp      eax, [esp+10h+ar2]
    jbe     short loc_36
    mov      esi, [esp+10h+ar2]
    sub      esi, eax
    lea      ecx, ds:0[edx*4]
    neg      esi
    cmp      ecx, esi
    jbe     short loc_55

loc_36: ; CODE XREF: f(int,int *,int *,int *)+21
    cmp      eax, [esp+10h+ar2]
    jnb     loc_143
    mov      esi, [esp+10h+ar2]
    sub      esi, eax
    lea      ecx, ds:0[edx*4]
    cmp      esi, ecx
    jb      loc_143

loc_55: ; CODE XREF: f(int,int *,int *,int *)+34
    cmp      eax, [esp+10h+ar1]
    jbe     short loc_67
    mov      esi, [esp+10h+ar2]
    sub      esi, eax
    neg      esi
    cmp      ecx, esi
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The SSE2-related instructions are:

- **MOVQDU (Move Unaligned Double Quadword)**—just loads 16 bytes from memory into a XMM-register.
- **PADDD (Add Packed Integers)**—adds 4 pairs of 32-bit numbers and leaves the result in the first operand. By the way, no exception is raised in case of overflow and no flags are to be set, just the low 32 bits of the result are to be stored. If one of PADDD’s operands is the address of a value in memory, then the address must be aligned on a 16-byte boundary. If it is not aligned, an exception will be triggered.
- **MOVDQA (Move Aligned Double Quadword)** is the same as MOVQDU, but requires the address of the value in memory to be aligned on a 16-bit boundary. If it is not aligned, exception will be raised.

185 MOVDQA works faster than MOVQDU, but requires aforesaid.

So, these SSE2-instructions are to be executed only in case there are more than 4 pairs to work on and the pointer ar3 is aligned on a 16-byte boundary.

185 More about data alignment: Wikipedia: Data structure alignment

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Also, if ar2 is aligned on a 16-byte boundary as well, this fragment of code is to be executed:

```
movdqu xmm0, xmmword ptr [ebx+edi*4]; ar1+i*4
paddd xmm0, xmmword ptr [esi+edi*4]; ar2+i*4
movdqa xmmword ptr [eax+edi*4], xmm0; ar3+i*4
```

Otherwise, the value from ar2 is to be loaded into XMM0 using MOVQ, which does not require aligned pointer, but may work slower:

```
movdqu xmm1, xmmword ptr [ebx+edi*4]; ar1+i*4
movdqu xmm0, xmmword ptr [esi+edi*4]; ar2+i*4 is not 16-byte aligned, so load it to XMM0
movdqa xmmword ptr [eax+edi*4], xmm1; ar3+i*4
```

In all other cases, non-SSE2 code is to be executed.

**GCC**

GCC may also vectorize in simple cases\(^{186}\), if the -O3 option is used and SSE2 support is turned on: -msse2.

What we get (GCC 4.4.1):

```
; f(int, int *, int *, int *)

Almost the same, however, not as meticulously as Intel C++.

Memory copy example

Let's revisit the simple memcpy() example (1.22.2 on page 197):

```c
#include <stdio.h>

void my_memcpy(unsigned char* dst, unsigned char* src, size_t cnt)
{
    size_t i;
    for (i=0; i<cnt; i++)
        dst[i]=src[i];
}
```

And that's what optimizations GCC 4.9.1 did:

Listing 1.396: Optimizing GCC 4.9.1 x64

```asm
my_memcpy:
; RDI = destination address
; RSI = source address
; RDX = size of block
    test  rdx, rdx
    je    .L41
    lea   rax, [rdi+16]
    cmp   rsi, rax
    lea   rax, [rsi+16]
    setae cl

I.36.2 SIMD strlen() implementation

It has to be noted that the SIMD instructions can be inserted in C/C++ code via special macros\(^{187}\). For MSVC, some of them are located in the intrin.h file.

It is possible to implement the strlen() function\(^{188}\) using SIMD instructions that works 2-2.5 times faster than the common implementation. This function loads 16 characters into a XMM-register and check each against zero\(^{189}\).

```c
size_t strlen_sse2(const char *str)
{
    register size_t len = 0;
    const char *s = str;
    bool str_isAligned = ((unsigned int)s)&0xFFFFFFF0 == (unsigned int)s;
    if (str_isAligned == false)
        return strlen (str);
    __m128i xmm0 = _mm_setzero_si128();
    __m128i xmm1;
    int mask = 0;
    for (; ;)
    {
        xmm1 = _mm_load_si128((__m128i *)s);
        xmm1 = _mm_cmpeq_epi8(xmm1, xmm0);
        if ((mask = _mm_movemask_epi8(xmm1)) != 0)
        {
            unsigned long pos;
            _BitScanForward(&pos, mask);
            len += (size_t)pos;
            break;
        }
        s += sizeof(__m128i);
        len += sizeof(__m128i);
    }
    return len;
}
```

Let's compile it in MSVC 2010 with /Ox option:

Listing 1.397: Optimizing MSVC 2010

```
_pos$75552 = -.4 ; size = 4
_str$ = 8 ; size = 4
?strlen_sse2@YAIPBD@Z PROC ; strlen_sse2
    push    ebp
    mov     ebp, esp
    and     esp, -16 ; ffffffff0H
    mov     eax, DWORD PTR _str$[ebp]
    sub     esp, 12 ; 0000000cH
    push    esi
    mov     esi, eax
    and     esi, -16 ; ffffffff0H
    xor     edx, edx
    mov     ecx, eax
    cmp     esi, eax
    je     SHORT $LN4@strlen_sse
    lea     edx, DWORD PTR [eax+1]
    npad    3 ; align next label
$LL11@strlen_sse:
    mov     cl, BYTE PTR [eax]
    inc     eax
    test    cl, cl
```

---

\(^{187}\)MSDN: MMX, SSE, and SSE2 Intrinsics

\(^{188}\)strlen() — standard C library function for calculating string length

\(^{189}\)The example is based on source code from: [http://go.yurichev.com/17330](http://go.yurichev.com/17330).
How it works? First of all, we must understand goal of the function. It calculates C-string length, but we can use different terms: it’s task is searching for zero byte, and then calculating its position relatively to string start.

First, we check if the str pointer is aligned on a 16-byte boundary. If not, we call the generic strlen() implementation.

Then, we load the next 16 bytes into the XMM1 register using MOVQ.

An observant reader might ask, why can’t MOVQ be used here since it can load data from the memory regardless pointer alignment?

Yes, it might be done in this way: if the pointer is aligned, load data using MOVQ, if not —use the slower MOVQ.

But here we are may hit another caveat:

In the Windows NT line of OS (but not limited to it), memory is allocated by pages of 4 KiB (4096 bytes). Each win32-process has 4 GiB available, but in fact, only some parts of the address space are connected to real physical memory. If the process is accessing an absent memory block, an exception is to be raised. That’s how VM works.

So, a function loading 16 bytes at once may step over the border of an allocated memory block. Let’s say that the OS has allocated 8192 (0x2000) bytes at address 0x008c0000. Thus, the block is the bytes starting from address 0x008c0000 to 0x008c1fff inclusive.

After the block, that is, starting from address 0x008c2000 there is nothing at all, e.g. the OS not allocated any memory there. Any attempt to access memory starting from that address will raise an exception.

And let’s consider the example in which the program is holding a string that contains 5 characters almost at the end of a block, and that is not a crime.
So, in normal conditions the program calls strlen(), passing it a pointer to the string 'hello' placed in memory at address 0x008c1ff8. strlen() reads one byte at a time until 0x008c1ffd, where there's a zero byte, and then it stops.

Now if we implement our own strlen() reading 16 bytes at once, starting at any address, aligned or not, MOVQDU may attempt to load 16 bytes at once at address 0x008c1ff8 up to 0x008c2008, and then an exception will be raised. That situation is to be avoided, of course.

So then we'll work only with the addresses aligned on a 16 bytes boundary, which in combination with the knowledge that the OS' page size is usually aligned on a 16-byte boundary gives us some warranty that our function will not read from unallocated memory.

Let's get back to our function.

_mm_setzero_si128()—is a macro generating pxor xmm0, xmm0—it just clears the XMM0 register.
_mm_load_si128()—is a macro for MOVDQA, it just loads 16 bytes from the address into the XMM1 register.
_mm_cmpeq_epi8()—is a macro for PCMPEQB, an instruction that compares two XMM-registers bytewise.
And if some byte is equals to the one in the other register, there will be 0xff at this point in the result or 0 if otherwise.

For example:

\[
\begin{array}{c}
XMM1: 0x11223344556677880000000000000000 \\
XMM0: 0x11ab34440078778811111111111111111
\end{array}
\]

After the execution of pcmpeqb xmm1, xmm0 the XMM1 register contains:

\[
XMM1: 0xff0000ff0000ffff0000000000000000
\]

In our case, this instruction compares each 16-byte block with a block of 16 zero-bytes, which has been set in the XMM0 register by pxor xmm0, xmm0.

The next macro is _mm_movemask_epi8()—that is the PMOVMSKB instruction.
It is very useful with PCMPEQB.

pmovmskb eax, xmm1

This instruction sets first EAX bit to 1 if the most significant bit of the first byte in XMM1 is 1. In other words, if the first byte of the XMM1 register is 0xff, then the first bit of EAX is to be 1, too.

If the second byte in the XMM1 register is 0xff, then the second bit in EAX is to be set to 1. In other words, the instruction is answering the question “which bytes in XMM1 has the most significant bit set, or greater than 0x7f”, and returns 16 bits in the EAX register. The other bits in the EAX register are to be cleared.

By the way, do not forget about this quirk of our algorithm. There might be 16 bytes in the input like:

\[
\begin{array}{ccccccccccccccccccc}
'h' & 'e' & 'l' & 'l' & 'o' & 0 & \text{garbage} & 0 & \text{garbage} \\
\end{array}
\]

It is the 'hello' string, terminating zero, and some random noise in memory.

If we load these 16 bytes into XMM1 and compare them with the zeroed XMM0, we are getting something like 191:

\[
XMM1: 0x0000ff0000000000ff00000000
\]

This means that the instruction found two zero bytes, and it is not surprising.

PMOVMSKB in our case will set EAX to 0b000100000001000000.

Obviously, our function must take only the first zero bit and ignore the rest.

\[191\]An order from MSB to LSB is used here.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The next instruction is BSF (Bit Scan Forward).

This instruction finds the first bit set to 1 and stores its position into the first operand.

EAX=0b0010000000100000

After the execution of bsf eax, eax, EAX contains 5, meaning 1 has been found at the 5th bit position (starting from zero).

MSVC has a macro for this instruction: _BitScanForward.

Now it is simple. If a zero byte has been found, its position is added to what we have already counted and now we have the return result.

Almost all.

By the way, it is also has to be noted that the MSVC compiler emitted two loop bodies side by side, for optimization.

By the way, SSE 4.2 (that appeared in Intel Core i7) offers more instructions where these string manipulations might be even easier: http://go.yurichev.com/17331

1.37 64 bits

1.37.1 x86-64

It is a 64-bit extension to the x86 architecture.

From the reverse engineer’s perspective, the most important changes are:

- Almost all registers (except FPU and SIMD) were extended to 64 bits and got a R- prefix. 8 additional registers were added. Now GPR’s are: RAX, RBX, RCX, RDX, RBP, RSP, RSI, RDI, R8, R9, R10, R11, R12, R13, R14, R15.

- It is still possible to access the older register parts as usual. For example, it is possible to access the lower 32-bit part of the RAX register using EAX:

```
<table>
<thead>
<tr>
<th>Byte number:</th>
</tr>
</thead>
<tbody>
<tr>
<td>7th</td>
</tr>
<tr>
<td>RAX&lt;64</td>
</tr>
<tr>
<td>EAX</td>
</tr>
<tr>
<td>AX</td>
</tr>
<tr>
<td>AH</td>
</tr>
</tbody>
</table>
```

The new R8-R15 registers also have their lower parts: R8D-R15D (lower 32-bit parts), R8W-R15W (lower 16-bit parts), R8L-R15L (lower 8-bit parts).

```
<table>
<thead>
<tr>
<th>Byte number:</th>
</tr>
</thead>
<tbody>
<tr>
<td>7th</td>
</tr>
<tr>
<td>R8</td>
</tr>
<tr>
<td>R8D</td>
</tr>
<tr>
<td>R8W</td>
</tr>
<tr>
<td>R8L</td>
</tr>
</tbody>
</table>
```

The number of SIMD registers was doubled from 8 to 16: XMM0-XMM15.

- In Win64, the function calling convention is slightly different, somewhat resembling fastcall (6.1.3 on page 734). The first 4 arguments are stored in the RCX, RDX, R8, R9 registers, the rest — in the stack. The caller function must also allocate 32 bytes so the callee may save there first 4 arguments and use these registers for its own needs. Short functions may use arguments just from registers, but larger ones may save their values on the stack.

System V AMD64 ABI (Linux, *BSD, Mac OS X) [Michael Matz, Jan Hubicka, Andreas Jaeger, Mark Mitchell, System V Application Binary Interface. AMD64 Architecture Processor Supplement, (2013)] also somewhat resembles fastcall, it uses 6 registers RDI, RSI, RDX, RCX, R8, R9 for the first 6 arguments. All the rest are passed via the stack.

See also the section on calling conventions (6.1 on page 733).

Also available as https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
• The C/C++ `int` type is still 32-bit for compatibility.

• All pointers are 64-bit now.

Since now the number of registers is doubled, the compilers have more space for maneuvering called register allocation. For us this implies that the emitted code containing less number of local variables.

For example, the function that calculates the first S-box of the DES encryption algorithm processes 32/64/128/256 values at once (depending on `DES_type` type (uint32, uint64, SSE2 or AVX)) using the bitslice DES method (read more about this technique here (1.36 on page 411)):

```c
/*
 * This software may be modified, redistributed, and used for any purpose,
 * so long as its origin is acknowledged.
 * Produced by Matthew Kwan - March 1998
 */

#ifdef _WIN64
#define DES_type unsigned __int64
#else
#define DES_type unsigned int
#endif

void s1 (DES_type a1, DES_type a2, DES_type a3, DES_type a4, DES_type a5, DES_type a6, DES_type *out1, DES_type *out2, DES_type *out3, DES_type *out4) {
    DES_type x1, x2, x3, x4, x5, x6, x7, x8;
    DES_type x9, x10, x11, x12, x13, x14, x15, x16;
    DES_type x17, x18, x19, x20, x21, x22, x23, x24;
    DES_type x25, x26, x27, x28, x29, x30, x31, x32;

Nothing was allocated in the local stack by the compiler, \texttt{x36} is synonym for \texttt{a5}.
By the way, there are CPUs with much more GPR’s, e.g. Itanium (128 registers).

1.37.2 ARM
64-bit instructions appeared in ARMv8.

1.37.3 Float point numbers
How floating point numbers are processed in x86-64 is explained here: 1.38.

1.37.4 64-bit architecture criticism
Some people has irritation sometimes: now one needs twice as much memory for storing pointers, including cache memory, despite the fact that x64 CPUs can address only 48 bits of external RAM.

Pointers have gone out of favor to the point now where I had to flame about it because on my 64-bit computer that I have here, if I really care about using the capability of my machine I find that I’d better not use pointers because I have a machine that has 64-bit registers but it only has 2 gigabytes of RAM. So a pointer never has more than 32 significant bits to it. But every time I use a pointer it’s costing me 64 bits and that doubles the size of my data structure. Worse, it goes into the cache and half of my cache is gone and that costs cash—cache is expensive.

So if I’m really trying to push the envelope now, I have to use arrays instead of pointers. I make complicated macros so that it looks like I’m using pointers, but I’m not really.

( Donald Knuth in “Coders at Work: Reflections on the Craft of Programming”. )
Some people make their own memory allocators. It’s interesting to know about CryptoMiniSat case. This program rarely uses more than 4GiB of RAM, but it uses pointers heavily. So it requires less memory on 32-bit architecture than on 64-bit one. To mitigate this problem, author made his own allocator (in \texttt{clauseallocator.h|cpp} files), which allows to have access to allocated memory using 32-bit identifiers instead of 64-bit pointers.

1.38 Working with floating point numbers using SIMD
Of course, the FPU has remained in x86-compatible processors when the SIMD extensions were added. The SIMD extensions (SSE2) offer an easier way to work with floating-point numbers.

The number format remains the same (IEEE 754).

So, modern compilers (including those generating for x86-64) usually use SIMD instructions instead of FPU ones.

It can be said that it’s good news, because it’s easier to work with them.

We are going to reuse the examples from the FPU section here: 1.25 on page 220.

1.38.1 Simple example

\url{https://github.com/msoos/cryptominisat/}

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
#include <stdio.h>

double f (double a, double b)
{
    return a/3.14 + b*4.1;
};

int main()
{
    printf ("%f
", f(1.2, 3.4));
};

x64

Listing 1.400: Optimizing MSVC 2012 x64

```
__real@4010666666666666 DQ 04010666666666666666r ; 4.1
__real@40091eb851eb851f DQ 040091eb851eb851fr ; 3.14

a$ = 8
b$ = 16
f PROC
    divsd xmm0, QWORD PTR __real@40091eb851eb851f
    mulsd xmm1, QWORD PTR __real@4010666666666666
    addsd xmm0, xmm1
    ret 0
f ENDP
```

The input floating point values are passed in the XMM0-XMM3 registers, all the rest—via the stack. $a$ is passed in XMM0, $b$—via XMM1.

The XMM-registers are 128-bit (as we know from the section about SIMD: 1.36 on page 410), but the double values are 64-bit, so only lower register half is used.

DIVSD is an SSE-instruction that stands for “Divide Scalar Double-Precision Floating-Point Values”, it just divides one value of type double by another, stored in the lower halves of operands.

The constants are encoded by compiler in IEEE 754 format.

MULSD and ADDSD work just as the same, but do multiplication and addition.

The result of the function’s execution in type double is left in the in XMM0 register.

That is how non-optimizing MSVC works:

Listing 1.401: MSVC 2012 x64

```
__real@4010666666666666 DQ 04010666666666666666r ; 4.1
__real@40091eb851eb851f DQ 040091eb851eb851fr ; 3.14

a$ = 8
b$ = 16
f PROC
    movsdx QWORD PTR [rsp+16], xmm1
    movsdx QWORD PTR [rsp+8], xmm0
    movsdx xmm0, QWORD PTR a$[rsp]
    divsd xmm0, QWORD PTR __real@40091eb851eb851f
    movsdx xmm1, QWORD PTR b$[rsp]
    mulsd xmm1, QWORD PTR __real@4010666666666666
    addsd xmm0, xmm1
    ret 0
f ENDP
```

Slightly redundant. The input arguments are saved in the “shadow space” (1.14.2 on page 100), but only their lower register halves, i.e., only 64-bit values of type double. GCC produces the same code.

---

195 MSDN: Parameter Passing

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's also compile this example for x86. Despite the fact it's generating for x86, MSVC 2012 uses SSE2 instructions:

Listing 1.402: Non-optimizing MSVC 2012 x86

```assembly
; tv70 = -8    ; size = 8
; a$ = 8      ; size = 8
; b$ = 16     ; size = 8

_f PROC
    push ebp
    mov ebp, esp
    sub esp, 8
    movsd xmm0, QWORD PTR _a$[ebp]
    divsd xmm0, QWORD PTR __real@40091eb851eb851f
    movsd xmm1, QWORD PTR _b$[ebp]
    mulsd xmm0, QWORD PTR __real@4010666666666666
    addsd xmm1, xmm0
    movsd QWORD PTR tv70[ebp], xmm0
    fld QWORD PTR tv70[ebp]
    mov esp, ebp
    pop ebp
    ret 0
_f ENDP
```

Listing 1.403: Optimizing MSVC 2012 x86

```assembly
; tv67 = 8    ; size = 8
; a$ = 8      ; size = 8
; b$ = 16     ; size = 8

_f PROC
    movsd xmm1, QWORD PTR _a$[esp-4]
    divsd xmm1, QWORD PTR __real@40091eb851eb851f
    movsd xmm0, QWORD PTR _b$[esp-4]
    mulsd xmm0, QWORD PTR __real@4010666666666666
    addsd xmm1, xmm0
    movsd QWORD PTR tv67[esp-4], xmm1
    fld QWORD PTR tv67[esp-4]
    ret 0
_f ENDP
```

It's almost the same code, however, there are some differences related to calling conventions: 1) the arguments are passed not in XMM registers, but in the stack, like in the FPU examples (1.25 on page 220); 2) the result of the function is returned in ST(0) — in order to do so, it's copied (through local variable tv) from one of the XMM registers to ST(0).
Let's try the optimized example in OllyDbg:

![OllyDbg screenshot]

Figure 1.114: OllyDbg: MOVSD loads the value of \( a \) into XMM1

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Figure 1.115: OllyDbg: DIVSD calculated **quotient** and stored it in XMM1.
Figure 1.116: OllyDbg: MULSD calculated product and stored it in XMM0
Figure 1.117: OllyDbg: ADDSD adds value in XMM0 to XMM1
We see that OllyDbg shows the XMM registers as pairs of *double* numbers, but only the lower part is used. Apparently, OllyDbg shows them in that format because the SSE2 instructions (suffixed with `-SD`) are executed right now.

But of course, it’s possible to switch the register format and to see their contents as 4 *float*-numbers or just as 16 bytes.
1.38.2 Passing floating point number via arguments

```c
#include <math.h>
#include <stdio.h>

int main ()
{
    printf ("32.01 ^ 1.54 = %lf\n", pow (32.01, 1.54));
    return 0;
}
```

They are passed in the lower halves of the XMM0-XMM3 registers.

```
Listing 1.404: Optimizing MSVC 2012 x64

SG1354 DB '32.01 ^ 1.54 = %lf', 0AH, 00H
__real@40400147ae147ae1 DQ 040400147ae147ae1
__real@3ff8a3d70a3d70a4 DQ 03ff8a3d70a3d70a4
main PROC
sub rsp, 40 ; 00000028H
movsd xmm1, QWORD PTR __real@3ff8a3d70a3d70a4
movsd xmm0, QWORD PTR __real@40400147ae147ae1
call pow
lea rcx, OFFSET FLAT:SG1354
movaps xmm1, xmm0
movd rdx, xmm1
call printf
xor eax, eax
add rsp, 40 ; 00000028H
ret
main ENDP
```

There is no MOVSDX instruction in Intel and AMD manuals (12.1.4 on page 986), there it is called just MOVSD. So there are two instructions sharing the same name in x86 (about the other see: .1.6 on page 1002). Apparently, Microsoft developers wanted to get rid of the mess, so they renamed it to MOVSDX. It just loads a value into the lower half of a XMM register.

`pow()` takes arguments from XMM0 and XMM1, and returns result in XMM0. It is then moved to RDX for `printf()`. Why? Maybe because `printf()`—is a variable arguments function?

```
Listing 1.405: Optimizing GCC 4.4.6 x64

.LC2:
.string "32.01 ^ 1.54 = %lf\n"
main:
sub rsp, 8
movsd xmm1, QWORD PTR .LC0[rip]
movsd xmm0, QWORD PTR .LC1[rip]
call pow
; result is now in XMM0
mov edi, OFFSET FLAT:.LC2
mov eax, 1 ; number of vector registers passed
call printf
xor eax, eax
add rsp, 8
ret
.LC0:
.long 171798692
.long 1073259479
.LC1:
.long 2920577761
.long 1077936455
```

GCC generates clearer output. The value for `printf()` is passed in XMM0. By the way, here is a case when 1 is written into EAX for `printf()`—this implies that one argument will be passed in vector registers, just
as the standard requires [Michael Matz, Jan Hubicka, Andreas Jaeger, Mark Mitchell, System V Application Binary Interface. AMD64 Architecture Processor Supplement, (2013)]

### 1.38.3 Comparison example

```c
#include <stdio.h>

double d_max (double a, double b) {
    if (a>b)
        return a;
    return b;
};

int main() {
    printf ("%f\n", d_max (1.2, 3.4));
    printf ("%f\n", d_max (5.6, -4));
};
```

**x64**

Listing 1.406: Optimizing MSVC 2012 x64

```
a$ = 8
b$ = 16
d_max PROC
    comisd xmm0, xmm1
    ja SHORT $LN2@d_max
    movaps xmm0, xmm1
$LN2@d_max:
    fatret 0
    jmp SHORT $LN2@d_max
    movsdx QWORD PTR [rsp+16], xmm1
    movsdx QWORD PTR [rsp+8], xmm0
    movsdx xmm0, QWORD PTR a$[rsp]
    comisd xmm0, QWORD PTR b$[rsp]
    jbe SHORT $LN1@d_max
    movsdx xmm0, QWORD PTR a$[rsp]
    jmp SHORT $LN2@d_max
$LN1@d_max:
    movsdx xmm0, QWORD PTR b$[rsp]
$LN2@d_max:
    fatret 0
    d_max ENDP
```

Optimizing MSVC generates a code very easy to understand.

COMISD is “Compare Scalar Ordered Double-Precision Floating-Point Values and Set EFLAGS”. Essentially, that is what it does.

Non-optimizing MSVC generates more redundant code, but it is still not hard to understand:

Listing 1.407: MSVC 2012 x64

```
a$ = 8
b$ = 16
d_max PROC
    movsdx QWORD PTR [rsp+16], xmm1
    movsdx QWORD PTR [rsp+8], xmm0
    movsdx xmm0, QWORD PTR a$[rsp]
    comisd xmm0, QWORD PTR b$[rsp]
    jbe SHORT $LN1@d_max
    movsdx xmm0, QWORD PTR a$[rsp]
    jmp SHORT $LN2@d_max
    movsdx xmm0, QWORD PTR b$[rsp]
$LN1@d_max:
    movsdx xmm0, QWORD PTR b$[rsp]
$LN2@d_max:
    fatret 0
    d_max ENDP
```

However, GCC 4.4.6 did more optimizations and used the MAXSD (“Return Maximum Scalar Double-Precision Floating-Point Value”) instruction, which just choose the maximum value!

Listing 1.408: Optimizing GCC 4.4.6 x64

d_max:
    maxsd     xmm0, xmm1
    ret
Let’s compile this example in MSVC 2012 with optimization turned on:

```
Listing 1.409: Optimizing MSVC 2012 x86

```

```
as = 8 ; size = 8
_bb = 16 ; size = 8
d_max PROC
  movsd xmm0, QWORD PTR _a$[esp-4]
  comisd xmm0, QWORD PTR _b$[esp-4]
  jbe SHORT $LN1@d_max
  fld QWORD PTR _a$[esp-4]
  ret

$LN1@d_max:
  _fild QWORD PTR _b$[esp-4]
  ret
_d_max ENDP
```

Almost the same, but the values of a and b are taken from the stack and the function result is left in ST(0).

If we load this example in OllyDbg, we can see how the COMISD instruction compares values and sets/clears the CF and PF flags:

![Figure 1.119: OllyDbg: COMISD changed CF and PF flags](image)

### 1.38.4 Calculating machine epsilon: x64 and SIMD

Let’s revisit the “calculating machine epsilon” example for *double* listing.1.32.2.

Now we compile it for x64:

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Listing 1.410: Optimizing MSVC 2012 x64

v$ = 8
calculate_machine_epsilon PROC
  movsdx QWORD PTR v$[rsp], xmm0
  movaps xmm1, xmm0
  inc QWORD PTR v$[rsp]
  movsdx xmm0, QWORD PTR v$[rsp]
  subsd xmm0, xmm1
ret 0

calculate_machine_epsilon ENDP

There is no way to add 1 to a value in 128-bit XMM register, so it must be placed into memory.

There is, however, the `ADDSD` instruction (Add Scalar Double-Precision Floating-Point Values) which can add a value to the lowest 64-bit half of a XMM register while ignoring the higher one, but MSVC 2012 probably is not that good yet.\(^{197}\)

Nevertheless, the value is then reloaded to a XMM register and subtraction occurs. `SUBSD` is “Subtract Scalar Double-Precision Floating-Point Values”, i.e., it operates on the lower 64-bit part of 128-bit XMM register. The result is returned in the XMM0 register.

### 1.38.5 Pseudo-random number generator example revisited

Let's revisit “pseudo-random number generator example” example listing.\(^{1.32.1}\)

If we compile this in MSVC 2012, it will use the SIMD instructions for the FPU.

Listing 1.411: Optimizing MSVC 2012

```
__real@3f800000 DD 03f800000r ; 1

; EAX=pseudorandom value
; and eax, 8388607 ; 007fffffffH
; or eax, 1065353216 ; 3f800000H
; EAX=pseudorandom value & 0x007fffffff | 0x3f800000
; store it into local stack:
  mov DWORD PTR _tmp$[esp+4], eax
; reload it as float point number:
  movss xmm0, DWORD PTR _tmp$[esp+4]
; subtract 1.0:
  subss xmm0, DWORD PTR __real@3f800000
; move value to ST0 by placing it in temporary variable...
  movss DWORD PTR tv128[esp+4], xmm0
; ... and reloading it into ST0:
  fld DWORD PTR tv128[esp+4]
  pop ecx
ret 0

?float_rand@YAMXZ ENDP
```

All instructions have the -SS suffix, which stands for “Scalar Single”.

“Scalar” implies that only one value is stored in the register.

“Single”\(^{198}\) stands for `float` data type.

### 1.38.6 Summary

Only the lower half of XMM registers is used in all examples here, to store number in IEEE 754 format.

\(^{197}\)As an exercise, you may try to rework this code to eliminate the usage of the local stack.

\(^{198}\)i.e., single precision.
Essentially, all instructions prefixed by -SD ("Scalar Double-Precision")—are instructions working with floating point numbers in IEEE 754 format, stored in the lower 64-bit half of a XMM register.

And it is easier than in the FPU, probably because the SIMD extensions were evolved in a less chaotic way than the FPU ones in the past. The stack register model is not used.

If you would try to replace double with float

in these examples, the same instructions will be used, but prefixed with -SS ("Scalar Single-Precision"), for example, MOVSS, COMISS, ADDSS, etc.

"Scalar" implies that the SIMD register containing only one value instead of several.

Instructions working with several values in a register simultaneously have “Packed” in their name.

Needless to say, the SSE2 instructions work with 64-bit IEEE 754 numbers (double), while the internal representation of the floating-point numbers in FPU is 80-bit numbers.

Hence, the FPU may produce less round-off errors and as a consequence, FPU may give more precise calculation results.

1.39 ARM-specific details

1.39.1 Number sign (#) before number

The Keil compiler, IDA and objdump precede all numbers with the “#” number sign, for example: listing.1.22.1.

But when GCC 4.9 generates assembly language output, it doesn’t, for example: listing.3.16.

The ARM listings in this book are somewhat mixed.

It’s hard to say, which method is right. Supposedly, one has to obey the rules accepted in environment he/she works in.

1.39.2 Addressing modes

This instruction is possible in ARM64:

```
ldr x0, [x29, 24]
```

This means add 24 to the value in X29 and load the value from this address.

Please note that 24 is inside the brackets. The meaning is different if the number is outside the brackets:

```
ldr w4, [x1], 28
```

This means load the value at the address in X1, then add 28 to X1.

ARM allows you to add or subtract a constant to/from the address used for loading.

And it’s possible to do that both before and after loading.

There is no such addressing mode in x86, but it is present in some other processors, even on PDP-11.

There is a legend that the pre-increment, post-increment, pre-decrement and post-decrement modes in PDP-11,

were “guilty” for the appearance of such C language (which developed on PDP-11) constructs as *ptr++, *++ptr, *ptr--, *--ptr.

By the way, this is one of the hard to memorize C features. This is how it is:

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
<table>
<thead>
<tr>
<th>C term</th>
<th>ARM term</th>
<th>C statement</th>
<th>how it works</th>
</tr>
</thead>
<tbody>
<tr>
<td>Post-increment</td>
<td>post-indexed addressing</td>
<td>*ptr++</td>
<td>use *ptr value, then increment ptr pointer</td>
</tr>
<tr>
<td>Post-decrement</td>
<td>post-indexed addressing</td>
<td>*ptr--</td>
<td>use *ptr value, then decrement ptr pointer</td>
</tr>
<tr>
<td>Pre-increment</td>
<td>pre-indexed addressing</td>
<td>*++ptr</td>
<td>increment ptr pointer, then use *ptr value</td>
</tr>
<tr>
<td>Pre-decrement</td>
<td>pre-indexed addressing</td>
<td>*--ptr</td>
<td>decrement ptr pointer, then use *ptr value</td>
</tr>
</tbody>
</table>

Pre-indexing is marked with an exclamation mark in the ARM assembly language. For example, see line 2 in listing.1.28.

Dennis Ritchie (one of the creators of the C language) mentioned that it presumably was invented by Ken Thompson (another C creator) because this processor feature was present in PDP-7 199, [Dennis M. Ritchie, The development of the C language, (1993)]200.

Thus, C language compilers may use it, if it is present on the target processor.

That’s very convenient for array processing.

### 1.39.3 Loading a constant into a register

#### 32-bit ARM

As we already know, all instructions have a length of 4 bytes in ARM mode and 2 bytes in Thumb mode. Then how can we load a 32-bit value into a register, if it’s not possible to encode it in one instruction? Let’s try:

```c
unsigned int f()
{
    return 0x12345678;
}
```

Listing 1.412: GCC 4.6.3 -O3 ARM mode

```assembly
f:
    ldr  r0, .L2
    bx   lr

.L2:       .word  305419896 ; 0x12345678
```

So, the 0x12345678 value is just stored aside in memory and loaded if needed.

But it’s possible to get rid of the additional memory access.

Listing 1.413: GCC 4.6.3 -O3 -march=armv7-a (ARM mode)

```assembly
mvw   r0, #22136 ; 0x5678
movt  r0, #4660 ; 0x1234
bx    lr
```

We see that the value is loaded into the register by parts, the lower part first (using MOVW), then the higher (using MOVT).

This implies that 2 instructions are necessary in ARM mode for loading a 32-bit value into a register.

It’s not a real problem, because in fact there are not many constants in real code (except of 0 and 1).

Does it mean that the two-instruction version is slower than one-instruction version?

Doubtfully. Most likely, modern ARM processors are able to detect such sequences and execute them fast.

On the other hand, IDA is able to detect such patterns in the code and disassembles this function as:

199 [http://yurichev.com/mirrors/C/c_dmr_postincrement.txt](http://yurichev.com/mirrors/C/c_dmr_postincrement.txt)
200 Also available as [http://go.yurichev.com/17264](http://go.yurichev.com/17264)

(For statistics collecting purposes) if you’ve read this far, please click [here](http://go.yurichev.com/17264). Thanks!
ARM64

uint64_t f()
{
    return 0x12345678ABCDEF01;
};

MOVK stands for “MOV Keep”, i.e., it writes a 16-bit value into the register, not touching the rest of the bits. The LSL suffix shifts left the value by 16, 32 and 48 bits at each step. The shifting is done before loading. This implies that 4 instructions are necessary to load a 64-bit value into a register.

Storing floating-point number into register

It’s possible to store a floating-point number into a D-register using only one instruction. For example:

double a()
{
    return 1.5;
};

The number 1.5 was indeed encoded in a 32-bit instruction. But how?

In ARM64, there are 8 bits in the FMOV instruction for encoding some floating-point numbers. The algorithm is called VFPExpandImm() in [ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile, (2013)]201. This is also called minifloat202.

We can try different values: the compiler is able to encode 30.0 and 31.0, but it couldn’t encode 32.0, as 8 bytes have to be allocated for this number in the IEEE 754 format:

double a()
{
    return 32;
};

(For statistics collecting purposes) if you’ve read this far, please click [here](http://yurichev.com/mirrors/ARMv8-A_Architecture_Reference_Manual_(Issue_A.a).pdf). Thanks!
1.39.4 Relocs in ARM64

As we know, there are 4-byte instructions in ARM64, so it is impossible to write a large number into a register using a single instruction.

Nevertheless, an executable image can be loaded at any random address in memory, so that’s why relocations exists. Read more about them (in relation to Win32 PE): 6.5.2 on page 759.

The address is formed using the ADRP and ADD instruction pair in ARM64.

The first loads a 4KiB-page address and the second one adds the remainder. Let’s compile the example from “Hello, world!” (listing 1.11) in GCC (Linaro) 4.9 under win32:

Listing 1.417: GCC (Linaro) 4.9 and objdump of object file

```bash
...>aarch64-linux-gnu-gcc.exe hw.c -c
...>aarch64-linux-gnu-objdump.exe -d hw.o
...
0000000000000000 <main>:
  0:  a9bf7bfd stp x29, x30, [sp,#-16]!
  4:  910003fd mov x29, sp
  8:  90000000 adrp x0, 0 <main>
 c:  91000000 add x0, x0, #0x0
10:  94000000 bl 0 <printf>
14:  52800000 mov w0, #0x0 // #0
18:  a8c17bfd ldp x29, x30, [sp],#16
1c:  d65f03c0 ret
...
RELOCATION RECORDS FOR [.text]:
OFFSET TYPE VALUE
0000000000000008 R_AARCH64_ADR_PREL_PG_HI21 .rodata
0000000000000000c R_AARCH64_ADD_ABS_LO12_NC .rodata
0000000000000010 R_AARCH64_CALL26 printf
```

So there are 3 relocations in this object file.

- The first one takes the page address, cuts the lowest 12 bits and writes the remaining high 21 bits to the ADRP instruction’s bit fields. This is because we don’t need to encode the low 12 bits, and the ADRP instruction has space only for 21 bits.
- The second one puts the 12 bits of the address relative to the page start into the ADD instruction’s bit fields.
- The last, 26-bit one, is applied to the instruction at address 0x10 where the jump to the printf() function is.

All ARM64 (and in ARM in ARM mode) instruction addresses have zeros in the two lowest bits (because all instructions have a size of 4 bytes), so one have to encode only the highest 26 bits of 28-bit address space (+128MB).

There are no such relocations in the executable file: because it’s known where the “Hello!” string is located, in which page, and the address of puts() is also known.

So there are values set already in the ADRP, ADD and BL instructions (the linker has written them while linking):

Listing 1.418: objdump of executable file

```bash
0000000000000000 <main>:
  0000000000000050 a9bf7bfd stp x29, x30, [sp,#-16]!
  0000000000000054 910003fd mov x29, sp
  0000000000000058 90000000 adrp x0, 0x0, 0x00000000 <init.-0x3b8>
  000000000000005c 91192000 add x0, x0, #0x648
  000000000000005e 97ffffa0 bl 0x040420 <puts@plt>
  0000000000000060 52800000 mov w0, #0x0 // #0
  0000000000000064 a8c17bfd ldp x29, x30, [sp],#16
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As an example, let’s try to disassemble the BL instruction manually. 0x97ffffffa0 is 0b10010111111111111111111110100000. According to [ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile, (2013)C5.6.26], imm26 is the last 26 bits: imm26 = 0b11111111111111111110100000. It is 0x3FFFFA0, but the MSB is 1, so the number is negative, and we can convert it manually to convenient form for us. By the rules of negation (2.2 on page 458), just invert all bits: (it is 0b1011111=0x5F), and add 1 (0x5F+1=0x60). So the number in signed form is -0x60. Let’s multiply -0x60 by 4 (because address stored in opcode is divided by 4): it is -0x180. Now let’s calculate destination address: 0x4005a0 + (-0x180) = 0x400420 (please note: we consider the address of the BL instruction, not the current value of PC, which may be different!). So the destination address is 0x400420.

More about ARM64-related relocs: [ELF for the ARM 64-bit Architecture (AArch64), (2013)]^{203}.

### 1.40 MIPS-specific details

#### 1.40.1 Loading a 32-bit constant into register

```
unsigned int f()
{
    return 0x12345678;
}
```

All instructions in MIPS, just like ARM, have a size of 32-bit, so it’s not possible to embed a 32-bit constant into one instruction.

So one have to use at least two instructions: the first loads the high part of the 32-bit number and the second one applies an OR operation, which effectively sets the low 16-bit part of the target register:

```
Listing 1.419: GCC 4.4.5 -O3 (assembly output)
li $2,305397760  # 0x12340000
j $31
ori $2,$2,0x5678 ; branch delay slot
```

IDA is fully aware of such frequently encountered code patterns, so, for convenience it shows the last ORI instruction as the LI pseudo instruction, which allegedly loads a full 32-bit number into the $V0 register.

```
Listing 1.420: GCC 4.4.5 -O3 (IDA)
lui $v0, 0x1234
jr $ra
li $v0, 0x12345678 ; branch delay slot
```

The GCC assembly output has the LI pseudo instruction, but in fact, LUI (“Load Upper Immediate”) is there, which stores a 16-bit value into the high part of the register.

Let’s see in objdump output:

```
Listing 1.421: objdump output:
00000000 <f>:
   0: 3c021234  lui v0,0x1234
   4: 03e00008  jr ra
   8: 34425678  ori v0,v0,0x5678
```

^{203}Also available as [http://go.yurichev.com/17288](http://go.yurichev.com/17288)
Loading a 32-bit global variable into register

```c
unsigned int global_var=0x12345678;
unsigned int f2()
{
    return global_var;
};
```

This is slightly different: LUI loads upper 16-bit from `global_var` into $2 (or $V0) and then LW loads lower 16-bits summing it with the contents of $2:

```
Listing 1.422: GCC 4.4.5 -O3 (assembly output)
f2:
    lui   $2,%hi(global_var)
    lw    $2,%lo(global_var)($2)
    j     $31
    nop ; branch delay slot
...
```

```
global_var:
    .word 305419896
```

**IDA** is fully aware of often used LUI/LW instruction pair, so it coalesces both into a single LW instruction:

```
Listing 1.423: GCC 4.4.5 -O3 (IDA)
_f2:
    lw   $v0, global_var
    jr   $ra
    or   $at, $zero ; branch delay slot
...
```

```
global_var: .globl global_var
    .word 0x12345678 # DATA XREF: _f2
```

`objdump`'s output is the same as GCC's assembly output. Let's also dump relocs of the object file:

```
Listing 1.424: objdump
objdump -D filename.o
...
00000000 <f2>:
  c:  3c020000  lui  v0,0x0
10:  8c420000  lw  v0,0(0v0)
14:  03e00000  jr   ra
18:  00200825  move at,at ; branch delay slot
1c:  00200825  move at,at

Disassembly of section .data:
00000000 <global_var>:
  0:  12345678  beq  s1,s4,159e4 <f2+0x159d8>
...

objdump -r filename.o
...
RELOCATION RECORDS FOR [.text]:
OFFSET TYPE    VALUE
00000000c R_MIPS_HI16 global_var
00000010c R_MIPS_LO16 global_var
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We can see that address of `global_var` is to be written right into LUI and LW instructions during executable file loading: high 16-bit part of `global_var` goes into the first one (LUI), lower 16-bit part goes into the second one (LW).

### 1.40.2 Further reading about MIPS

Chapter 2

Important fundamentals
2.1 Integral datatypes

Integral datatype is a type for a value which can be converted to number. These are numbers, enumerations, booleans.

2.1.1 Bit

Obvious usage for bits are boolean values: 0 for false and 1 for true.

Set of booleans can be packed into word: there will be 32 booleans in 32-bit word, etc. This way is called bitmap or bitfield.

But it has obvious overhead: a bit jiggling, isolating, etc. While using word (or int type) for boolean variable is not economic, but highly efficient.

In C/C++ environment, 0 is for false and any non-zero value is for true. For example:

```c
if (1234)
  printf ("this will always be executed\n");
else
  printf ("this will never\n");
```

This is popular way of enumerating characters in a C-string:

```c
char *input=...;
while(*input) // execute body if *input character is non-zero
{
  // do something with *input
  input++;
}
```

2.1.2 Nibble AKA nybble

AKA half-byte, tetrade. Equals to 4 bits.

All these terms are still in use today.

Binary-coded decimal (BCD)

4-bit nibbles were used in 4-bit CPUs like legendary Intel 4004 (used in calculators).

It’s interesting to know that there was binary-coded decimal (BCD) way of representing decimal digit using 4 bits. Decimal 0 is represented as 0b0000, decimal 9 as 0b1001 and higher values are not used. Decimal 1234 is represented as 0x1234. Of course, this way is not economical.

Nevertheless, it has one advantage: decimal to BCD-packed number conversion and back is extremely easy. BCD-numbers can be added, subtracted, etc., but an additional correction is needed. x86 CPUs has rare instructions for that: AAA/DAA (adjust after addition), AAS/DAS (adjust after subtraction), AAM (after multiplication), AAD (after division).

The need for CPUs to support BCD numbers is a reason why half-carry flag (on 8080/Z80) and auxiliary flag (AF on x86) are exist: this is carry-flag generated after proceeding of lower 4 bits. The flag is then used for adjustment instructions.

The fact of easy conversion had led to popularity of [Peter Abel, IBM PC assembly language and programming (1987)] book. But aside of this book, the author of these notes never seen BCD numbers in practice, except for magic numbers (5.6.1 on page 711), like when someone’s birthday is encoded like 0x19791011—this is indeed packed BCD number.

Surprisingly, the author found a use of BCD-encoded numbers in SAP software: [https://yurichev.com/blog/SAP/]. Some numbers, including prices, are encoded in BCD form in database. Perhaps, they used it to make it compatible with some ancient software/hardware?

1 Binary-Coded Decimal
**BCD** instructions in x86 were often used for other purposes, especially in undocumented ways, for example:

```
  cmp al,10
  sbb al,69h
  das
```

This obscure code converts number in 0..15 range into **ASCII** character ‘0’..'9', ‘A’..'F'.

**Z80**

Z80 was clone of 8-bit Intel 8080 CPU, and because of space constraints, it has 4-bit **ALU**, i.e., each operation over two 8-bit numbers had to be proceeded in two steps. One side-effect of this was easy and natural generation of **half-carry flag**.

### 2.1.3 Byte

Byte is primarily used for character storage. 8-bit bytes were not common as today. Punched tapes for teletypes had 5 and 6 possible holes, this is 5 or 6 bits for byte.

To emphasize the fact the byte has 8 bits, byte is sometimes called **octet**: at least **fetchmail** uses this terminology.

9-bit bytes used to exist in 36-bit architectures: 4 9-bit bytes would fit in a single word. Probably because of this fact, C/C++ standard tells that **char** has to have a room for at least 8 bits, but more bits are allowable.

For example, in the early C language manual[^2], we can find this:

```
char one byte character (PDP-11, IBM360: 8 bits; H6070: 9 bits)
```

By H6070 they probably meant Honeywell 6070, with 36-bit words.

**Standard ASCII table**

7-bit ASCII table is standard, which has only 128 possible characters. Early E-Mail transport software were operating only on 7-bit ASCII codes, so a **MIME**[^3] standard needed to encode messages in non-Latin writing systems. 7-bit ASCII code was augmented by parity bit, resulting in 8 bits.

**Data Encryption Standard** (DES[^4]) has a 56 bits key, this is 8 7-bit bytes, leaving a space to parity bit for each character.

There is no need to memorize whole ASCII table, but rather ranges. [0..0x1F] are control characters (non-printable). [0x20..0x7E] are printable ones. Codes starting at 0x80 are usually used for non-Latin writing systems and/or pseudographics.

Significant codes which will be easily memorized are: 0 (end of C-string, ‘\0’ in C/C++); 0xA or 10 (line feed, ‘\n’ in C/C++); 0xD or 13 (carriage return, ‘\r’ in C/C++).

0x20 (space) is also often memorized.

**8-bit CPUs**

x86 has capability to work with byte(s) on register level (because they are descendants of 8-bit 8080 CPU), RISC CPUs like ARM and MIPS—not.

[^2]: https://yurichev.com/mirrors/C/bwk-tutor.html
[^3]: Multipurpose Internet Mail Extensions
[^4]: Data Encryption Standard
2.1.4 Widechar

This is an attempt to support multi-lingual environment by extending byte to 16-bit. Most well-known example is Windows NT kernel and win32 functions with \textit{W} suffix. This is why each Latin character in plain English text string is interleaved with zero byte. This encoding is called UCS-2 or UTF-16.

Usually, \texttt{wchar_t} is synonym to 16-bit \textit{short} data type.

2.1.5 Signed integer vs unsigned

Some may argue, why unsigned data types exist at first place, since any unsigned number can be represented as signed. Yes, but absence of sign bit in a value extends its range twice. Hence, signed byte has range of -128..127, and unsigned one: 0..255. Another benefit of using unsigned data types is self-documenting: you define a variable which can’t be assigned to negative values.

Unsigned data types are absent in Java, for which it’s criticized. It’s hard to implement cryptographical algorithms using boolean operations over signed data types.

Values like 0xFFFFFFFF (-1) are used often, mostly as error codes.

2.1.6 Word

\texttt{Word} word is somewhat ambiguous term and usually denotes a data type fitting in \texttt{GPR}. Bytes are practical for characters, but impractical for other arithmetical calculations.

Hence, many CPUs have \texttt{GPR}s with width of 16, 32 or 64 bits. Even 8-bit CPUs like 8080 and Z80 offer to work with 8-bit register pairs, each pair forming a 16-bit \texttt{pseudoregister} (\texttt{BC}, \texttt{DE}, \texttt{HL}, etc.). Z80 has some capability to work with register pairs, and this is, in a sense, some kind of 16-bit CPU emulation.

In general, if a CPU marketed as “\textit{n-bit CPU}”, this usually means it has \textit{n-bit GPR}s.

There was a time when hard disks and \texttt{RAM} modules were marketed as having \textit{n} kilo-words instead of \textit{b} kilobytes/megabytes.

For example, \textit{Apollo Guidance Computer}\footnote{https://en.wikipedia.org/wiki/Apollo_Guidance_Computer} has 2048 words of \texttt{RAM}. This was a 16-bit computer, so there was 4096 bytes of \texttt{RAM}.

\textit{TX-0}\footnote{https://en.wikipedia.org/wiki/TX-0} had 64K of 18-bit words of magnetic core memory, i.e., 64 kilo-words.

\textit{DECSYSTEM-2060}\footnote{https://en.wikipedia.org/wiki/DECSYSTEM-20} could have up to 4096 kilowords of \textit{solid state memory} (i.e., hard disks, tapes, etc). This was 36-bit computer, so this is 18432 kilobytes or 18 megabytes.

Essentially, why do you need bytes if you have words? Mostly for text strings processing. Words can be used in almost any other situations.

\begin{itemize}
\item \texttt{int} in C/C++ is almost always mapped to \texttt{word}. (Except of AMD64 architecture where \texttt{int} is still 32-bit one, perhaps, for the reason of better portability.)
\item \texttt{int} is 16-bit on PDP-11 and old MS-DOS compilers. \texttt{int} is 32-bit on VAX, on x86 starting at 80386, etc.
\item Even more than that, if type declaration for a variable is omitted in C/C++ program, \texttt{int} is used silently by default. Perhaps, this is inheritance of B programming language\footnote{http://yurichev.com/blog/typeless/}.
\end{itemize}

\texttt{GPR} is usually fastest container for variable, faster than packed bit, and sometimes even faster than byte (because there is no need to isolate a single bit/byte from \texttt{GPR}). Even if you use it as a container for loop counter in 0..99 range.
**Word** in assembly language is still 16-bit for x86, because it was so for 16-bit 8086. **Double word** is 32-bit, **quad word** is 64-bit. That’s why 16-bit words are declared using DW in x86 assembly, 32-bit ones using DD and 64-bit ones using DQ.

**Word** is 32-bit for ARM, MIPS, etc., 16-bit data types are called **half-word** there. Hence, **double word** on 32-bit RISC is 64-bit data type.

**GDB** has the following terminology: **halfword** for 16-bit, **word** for 32-bit and **giant word** for 64-bit.

16-bit C/C++ environment on PDP-11 and MS-DOS has **long** data type with width of 32 bits, perhaps, they meant **long word** or **long int**?

32-bit C/C++ environment has **long long** data type with width of 64 bits.

Now you see why the **word** word is ambiguous.

**Should I use int?**

Some people argue that int shouldn’t be used at all, because it ambiguity can lead to bugs. For example, well-known **lzhuf** library uses int at one point and everything works fine on 16-bit architecture. But if ported to architecture with 32-bit int, it can crash: [http://yurichev.com/blog/lzhuf/](http://yurichev.com/blog/lzhuf/).

Less ambiguous types are defined in **stdint.h** file: uint8_t, uint16_t, uint32_t, uint64_t, etc.

Some people like Donald E. Knuth proposed more sonorous words for these types: byte/wyde/tetabyte/octabyte. But these names are less popular than clear terms with inclusion of u (unsigned) character and number right into the type name.

**Word-oriented computers**

Despite the ambiguity of the **word** term, modern computers are still word-oriented: RAM and all levels of cache are still organized by words, not by bytes. However, size in bytes is used in marketing.

Access to RAM/cache by address aligned by word boundary is often cheaper than non-aligned.

During data structures development, which are supposed to be fast and efficient, one should always take into consideration length of the **word** on the CPU to be executed on. Sometimes the compiler will do this for programmer, sometimes not.

2.1.7 **Address register**

For those who fostered on 32-bit and/or 64-bit x86, and/or RISC of 90s like ARM, MIPS, PowerPC, it’s natural that address bus has the same width as **GPR** or **word**. Nevertheless, width of address bus can be different on other architectures.

8-bit Z80 can address $2^{16}$ bytes, using 8-bit registers pairs or dedicated registers (IX, IY). **SP** and **PC** registers are also 16-bit ones.

Cray-1 supercomputer has 64-bit GPRs, but 24-bit address registers, so it can address $2^{24}$ (16 megawords or 128 megabytes). RAM was very expensive in 1970s, and a typical Cray had 1048576 (0x100000) words of RAM or 8MB. So why to allocate 64-bit register for address or pointer?

8086/8088 CPUs had a really weird addressing scheme: values of two 16-bit registers were summed in a weird manner resulting in a 20-bit address. Perhaps, this was some kind of toy-level virtualization (11.6 on page 976)? 8086 could run several programs (not simultaneously, though).

Early ARM1 has an interesting artifact:

> Another interesting thing about the register file is the **PC** register is missing a few bits. Since the ARM1 uses 26-bit addresses, the top 6 bits are not used. Because all instructions are aligned on a 32-bit boundary, the bottom two address bits in the **PC** are always zero. These 8 bits are not only unused, they are omitted from the chip entirely.

Hence, it's physically not possible to push a value with one of two last bits set into PC register. Nor it's possible to set any bits in high 6 bits of PC.

x86-64 architecture has virtual 64-bit pointers/addresses, but internally, width of address bus is 48 bits (seems enough to address 256TB of RAM).

2.1.8 Numbers

What are numbers used for?

When you see some number(s) altering in a CPU register, you may be interested in what this number means. It's an important skill for a reverse engineer to determine possible data type from a set of changing numbers.

Boolean

If the number is switching from 0 to 1 and back, most chances that this value has boolean data type.

Loop counter, array index

Variable increasing from 0, like: 0, 1, 2, 3...—a good chance this is a loop counter and/or array index.

Signed numbers

If you see a variable which holds very low numbers and sometimes very high numbers, like 0, 1, 2, 3, and $0xFFFFFFFF$, $0xFFFFFFFE$, $0xFFFFFFFD$, there's a good chance it is a signed variable in two's complement form (2.2 on page 458), and last 3 numbers are -1, -2, -3.

32-bit numbers

There are numbers so large\(^\text{10}\), that there is even a special notation which exists to represent them (Knuth's up-arrow notation\(^\text{11}\)). These numbers are so large so these are not practical for engineering, science and mathematics.

Almost all engineers and scientists are happy with IEEE 754 double precision floating point, which has maximal value around $1.8 \times 10^{308}$. (As a comparison, the number of atoms in the observable universe, is estimated to be between $4 \times 10^{79}$ and $4 \times 10^{81}$.)

In fact, upper bound in practical computing is much, much lower. In MS-DOS era 16-bit int was used almost for everything (array indices, loop counters), while 32-bit long was used rarely.

During advent of x86-64, it was decided for int to stay as 32 bit size integer, because, probably, usage of 64-bit int is even rarer.

I would say, 16-bit numbers in range 0..65535 are probably most used numbers in computing.

Given that, if you see unusually large 32-bit value like 0x87654321, this is a good chance this can be:

- this can still be a 16-bit number, but signed, between 0xFFFF8000 (-32768) and 0xFFFFFFFF (-1).
- address of memory cell (can be checked using memory map feature of debugger).
- packed bytes (can be checked visually).
- bit flags.
- something related to (amateur) cryptography.
- magic number (5.6.1 on page 711).
- IEEE 754 floating point number (can also be checked).

\(^{11}\)https://en.wikipedia.org/wiki/Knuth%27s_up-arrow_notation

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Almost same story for 64-bit values.

...so 16-bit int is enough for almost everything?

It’s interesting to note: in [Michael Abrash, *Graphics Programming Black Book*, 1997 chapter 13] we can find that there are plenty cases in which 16-bit variables are just enough. In a meantime, Michael Abrash has a pity that 80386 and 80486 CPUs has so little available registers, so he offers to put two 16-bit values into one 32-bit register and then to rotate it using ROR reg, 16 (on 80386 and later) (ROL reg, 16 will also work) or BSWAP (on 80486 and later) instruction.

That reminds us Z80 with alternate pack of registers (suffixed with apostrophe), to which CPU can switch (and then switch back) using EXX instruction.

**Size of buffer**

When a programmer needs to declare the size of some buffer, values in form of \(2^n\) are usually used (512 bytes, 1024, etc.). Values in \(2^n\) form are easily recognizable ([1.28.5 on page 325](#)) in decimal, hexadecimal and binary base.

But needless to say, programmers are still humans with their decimal culture. And somehow, in DBMS area, size of textual database fields is often chosen as \(10^n\) number, like 100, 200. They just think “Okay, 100 is enough, wait, 200 will be better”. And they are right, of course.

Maximum width of VARCHAR2 data type in Oracle RDBMS is 4000 characters, not 4096. There is nothing wrong with this, this is just a place where numbers like \(10^n\) can be encountered.

**Address**

It’s always a good idea to keep in mind an approximate memory map of the process you currently debug. For example, many win32 executables started at 0x00401000, so an address like 0x00451230 is probably located inside executable section. You’ll see addresses like these in the EIP register.

Stack is usually located somewhere below.

Many debuggers are able to show the memory map of the debuggee, for example: [1.12.3 on page 79](#).

If a value is increasing by step 4 on 32-bit architecture or by step 8 on 64-bit one, this probably sliding address of some elements of array.

It’s important to know that win32 doesn’t use addresses below 0x10000, so if you see some number below this constant, this cannot be an address (see also: [https://msdn.microsoft.com/en-us/library/ms810627.aspx](https://msdn.microsoft.com/en-us/library/ms810627.aspx)).

Anyway, many debuggers can show you if the value in a register can be an address to something. OllyDbg can also show an ASCII string if the value is an address of it.

**Bit field**

If you see a value where one (or more) bit(s) are flipping from time to time like 0xABCD1234 \(\rightarrow\) 0xABCD1434 and back, this is probably a bit field (or bitmap).

**Packed bytes**

When `strcmp()` or `memcmp()` copies a buffer, it loads/stores 4 (or 8) bytes simultaneously, so if a string containing “4321“, and it would be copied to another place, at one point you’ll see 0x31323334 value in some register. This is 4 packed bytes into a 32-bit value.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
### 2.2 Signed number representations

There are several methods for representing signed numbers\(^\text{12}\), but “two’s complement” is the most popular one in computers.

Here is a table for some byte values:

<table>
<thead>
<tr>
<th>binary</th>
<th>hexadecimal</th>
<th>unsigned</th>
<th>signed</th>
</tr>
</thead>
<tbody>
<tr>
<td>01111111</td>
<td>0x7f</td>
<td>127</td>
<td>127</td>
</tr>
<tr>
<td>01111110</td>
<td>0x7e</td>
<td>126</td>
<td>126</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>00000110</td>
<td>0x6</td>
<td>6</td>
<td>6</td>
</tr>
<tr>
<td>00000101</td>
<td>0x5</td>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>00000100</td>
<td>0x4</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>00000011</td>
<td>0x3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>00000010</td>
<td>0x2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>00000001</td>
<td>0x1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>00000000</td>
<td>0x0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>11111111</td>
<td>0xff</td>
<td>255</td>
<td>-1</td>
</tr>
<tr>
<td>11111110</td>
<td>0xfe</td>
<td>254</td>
<td>-2</td>
</tr>
<tr>
<td>11111101</td>
<td>0xfd</td>
<td>253</td>
<td>-3</td>
</tr>
<tr>
<td>11111100</td>
<td>0xfc</td>
<td>252</td>
<td>-4</td>
</tr>
<tr>
<td>11111011</td>
<td>0xfb</td>
<td>251</td>
<td>-5</td>
</tr>
<tr>
<td>11111010</td>
<td>0xfa</td>
<td>250</td>
<td>-6</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10000010</td>
<td>0x82</td>
<td>130</td>
<td>-126</td>
</tr>
<tr>
<td>10000001</td>
<td>0x81</td>
<td>129</td>
<td>-127</td>
</tr>
<tr>
<td>10000000</td>
<td>0x80</td>
<td>128</td>
<td>-128</td>
</tr>
</tbody>
</table>

The difference between signed and unsigned numbers is that if we represent 0xFFFFFFFFE and 0x00000002 as unsigned, then the first number (4294967294) is bigger than the second one (2). If we represent them both as signed, the first one becomes \(-2\), and it is smaller than the second (2). That is the reason why conditional jumps (1.18 on page 124) are present both for signed (e.g. JG, JL) and unsigned (JA, JB) operations.

For the sake of simplicity, this is what one needs to know:

- Numbers can be signed or unsigned.
- C/C++ signed types:
  - int64_t (-9,223,372,036,854,775,808 .. 9,223,372,036,854,775,807) (- 9.2.. 9.2 quintillions) or 0x8000000000000000..0x7FFFFFFFFFFFFFFF,
  - int (-2,147,483,648..2,147,483,647 (- 2.15.. 2.15Gb) or 0x80000000..0x7FFFFFFF,
  - char (-128..127 or 0x80..0x7F),
  - ssize_t.
- Unsigned:
  - uint64_t (0..18,446,744,073,709,551,615 (18 quintillions) or 0..0xFFFFFFFFFFFFFFFF,
  - unsigned int (0..4,294,967,295 (4.3Gb) or 0..0xFFFFFFFF,
  - unsigned char (0..255 or 0..0xFF),
  - size_t.
- Signed types have the sign in the MSB: 1 means “minus”, 0 means “plus”.
- Promoting to a larger data types is simple: 1.34.5 on page 407.
- Negation is simple: just invert all bits and add 1.

We can keep in mind that a number of inverse sign is located on the opposite side at the same proximity from zero. The addition of one is needed because zero is present in the middle.

\(^{12}\text{wikipedia}\)

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
• The addition and subtraction operations work well for both signed and unsigned values. But for multiplication and division operations, x86 has different instructions: IDIV/IMUL for signed and DIV/MUL for unsigned.

• Here are some more instructions that work with signed numbers:
  CBW/CWD/CWDE/CDQ/CDQE (.1.6 on page 1004), MOVVSX (.1.23.1 on page 204), SAR (.1.6 on page 1008).

A table of some negative and positive values ( ?? on page ??) looks like thermometer with Celsius scale. This is why addition and subtraction works equally well for both signed and unsigned numbers: if the first addend is represented as mark on thermometer, and one need to add a second addend, and it’s positive, we just shift mark up on thermometer by the value of second addend. If the second addend is negative, then we shift mark down to absolute value of the second addend.

Addition of two negative numbers works as follows. For example, we need to add -2 and -3 using 16-bit registers. -2 and -3 is 0xfffe and 0xfffd respectively. If we add these numbers as unsigned, we get 0x0ffe+0xfffd=0x1fffb. But we work on 16-bit registers, so the result is cut off, the first 1 is dropped, 0xfffb is left, and this is -5. This works because -2 (or 0xfffe) can be represented using plain English like this: “2 lacks in this value up to maximal value in 16-bit register + 1”. -3 can be represented as “…3 lacks in this value up to ...”. Maximal value of 16-bit register + 1 is 0x10000. During addition of two numbers and cutting off by \(2^{16}\) modulo, \(2 + 3 = 5\) will be lacking.

### 2.2.1 Using IMUL over MUL

Example like listing.3.21.2 where two unsigned values are multiplied compiles into listing.3.21.2 where IMUL is used instead of MUL.

This is important property of both MUL and IMUL instructions. First of all, they both produce 64-bit value if two 32-bit values are multiplied, or 128-bit value if two 64-bit values are multiplied (biggest possible product in 32-bit environment is \(0xffffffff*0xffffffff=0xfffffffff00000001\)). But C/C++ standards have no way to access higher half of result, and a product always has the same size as multiplicands. And both MUL and IMUL instructions works in the same way if higher half is ignored, i.e., they both generate the same lower half. This is important property of “two’s complement” way of representing signed numbers.

So C/C++ compiler can use any of these instructions.

But IMUL is more versatile than MUL because it can take any register(s) as source, while MUL requires one of multiplicands stored in AX/EAX/RAX register. Even more than that: MUL stores result in EDX:EAX pair in 32-bit environment, or RDX:RAX in 64-bit one, so it always calculates the whole result. On contrary, it’s possible to set a single destination register while using IMUL instead of pair, and then CPU will calculate only lower half, which works faster [see Torbom Granlund, Instruction latencies and throughput for AMD and Intel x86 processors].

Given than, C/C++ compilers may generate IMUL instruction more often then MUL.

Nevertheless, using compiler intrinsic, it’s still possible to do unsigned multiplication and get full result. This is sometimes called extended multiplication. MSVC has intrinsic for this called __emu\(^{13}\) and another one: _umul128\(^{15}\). GCC offer __int128 data type, and if 64-bit multiplicands are first promoted to 128-bit ones, then a product is stored into another __int128 value, then result is shifted by 64 bits right, you’ll get higher half of result\(^{16}\).

**MulDiv() function in Windows**

Windows has MulDiv() function \(^{17}\), fused multiply/divide function, it multiplies two 32-bit integers into intermediate 64-bit value and then divides it by a third 32-bit integer. It is easier than to use two compiler intrinsic, so Microsoft developers made a special function for it. And it seems, this is busy function, judging by its usage.

### 2.2.2 Couple of additions about two’s complement form

Exercise 2-1. Write a program to determine the ranges of char, short, int, and long variables, both signed and unsigned, by printing appropriate values from standard headers and by direct computation.

#### Getting maximum number of some word

Maximum unsigned number is just a number where all bits are set: *0xFF....FF* (this is -1 if the word is treated as signed integer). So you take a word, set all bits and get the value:

```c
#include <stdio.h>

int main()
{
    unsigned int val=~0; // change to "unsigned char" to get maximal value for the unsigned 8-bit byte
    // 0-1 will also work, or just -1
    printf("%u\n", val); //
}
```

This is 4294967295 for 32-bit integer.

#### Getting minimum number for some signed word

Minimum signed number is encoded as *0x80....00*, i.e., most significant bit is set, while others are cleared. Maximum signed number is encoded in the same way, but all bits are inverted: *0x7F....FF*.

Let's shift a lone bit left until it disappears:

```c
#include <stdio.h>

int main()
{
    signed int val=1; // change to "signed char" to find values for signed byte
    while (val!=0)
    {
        printf("%d %d\n", val, ~val);
        val=val<<1;
    }
}
```

Output is:

```
... 
536870912 -536870913 
1073741824 -1073741825 
-2147483648 2147483647 
```

Two last numbers are minimum and maximum signed 32-bit *int* respectively.

#### 2.2.3 −1

Now you see that −1 is when all bits are set. Often, you can find the −1 constant in all sorts of code, where a constant with all bits set are needed, for example, a mask.

For example: 3.16.1 on page 534.
2.3 Integer overflow

I intentionally put this section after the section about signed number representation.

First, take a look at this implementation of `itoa()` function from [Brian W. Kernighan, Dennis M. Ritchie, *The C Programming Language*, 2ed, (1988)]:

```c
void itoa(int n, char s[])
{
    int i, sign;
    if ((sign = n) < 0) /* record sign */
        n = -n; /* make n positive */
    i = 0;
    do { /* generate digits in reverse order */
        s[i++] = n % 10 + '0'; /* get next digit */
    } while ((n /= 10) > 0); /* delete it */
    if (sign < 0)
        s[i++] = '-';
    s[i] = '\0';
    strrev(s);
}
```

(The full source code: [https://github.com/DennisYurichev/RE-for-beginners/blob/master/fundamentals/itoa_KR.c](https://github.com/DennisYurichev/RE-for-beginners/blob/master/fundamentals/itoa_KR.c))

It has a subtle bug. Try to find it. You can download source code, compile it, etc. The answer on the next page.
Exercise 3-4. In a two's complement number representation, our version of `itoa` does not handle the largest negative number, that is, the value of \( n \) equal to \(-2^{\text{wordsize}-1}\). Explain why not. Modify it to print that value correctly, regardless of the machine on which it runs.

The answer is: the function cannot process largest negative number (\texttt{INT\_MIN} or \texttt{0x80000000} or \texttt{-2147483648}) correctly.

How to change sign? Invert all bits and add 1. If to invert all bits in \texttt{INT\_MIN} value (\texttt{0x80000000}), this is \texttt{0x7fffffff}. Add 1 and this is \texttt{0x80000000} again. So changing sign has no effect. This is an important artifact of two's complement system.

Further reading:
- blexim – Basic Integer Overflows\(^\text{18}\)
- Yannick Moy, Nikolaj Bjørner, and David Sielaff – Modular Bug-finding for Integer Overflows in the Large: Sound, Efficient, Bit-precise Static Analysis\(^\text{19}\)

### 2.4 AND

#### 2.4.1 Checking if a value is on \(2^n\) boundary

If you need to check if your value is divisible by \(2^n\) number (like 1024, 4096, etc.) without remainder, you can use a \texttt{%} operator in C/C++, but there is a simpler way. 4096 is \texttt{0x1000}, so it always has \(4 \times 3 = 12\) lower bits cleared.

What you need is just:

```c
if (value&0xFFF)
{
    printf ("value is not divisible by 0x1000 (or 4096)\n");
    printf ("by the way, remainder is \%d\n", value&0xFFF);
}
el
else
    printf ("value is divisible by 0x1000 (or 4096)\n");
```

In other words, this code checks if there are any bit set among lower 12 bits. As a side effect, lower 12 bits is always a remainder from division a value by 4096 (because division by \(2^n\) is merely a right shift, and shifted (and dropped) bits are bits of remainder).

Same story if you want to check if the number is odd or even:

```c
if (value&1)
    // odd
else
    // even
```

This is merely the same as if to divide by 2 and get 1-bit remainder.

#### 2.4.2 KOI-8R Cyrillic encoding

It was a time when 8-bit ASCII table wasn’t supported by some Internet services, including email. Some supported, some others—not.

It was also a time, when non-Latin writing systems used second half of 8-bit ASCII table to accommodate non-Latin characters. There were several popular Cyrillic encodings, but KOI-8R (devised by Andrey “ache” Chernov) is somewhat unique in comparison with others.

\(^\text{18}\)http://phrack.org/issues/60/10.html

\(^\text{19}\)https://yurichev.com/mirrors/SMT/z3prefix.pdf

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Someone may notice that Cyrillic characters are allocated almost in the same sequence as Latin ones. This leads to one important property: if all 8th bits in Cyrillic text encoded in KOI-8R are to be reset, a text transforms into transliterated text with Latin characters in place of Cyrillic. For example, Russian sentence:

Мой дядя самых честных правил, Когда не в шутку занемог, Он уважать себя заставил, И лучше выдумать не мог.

...if encoded in KOI-8R and then 8th bit stripped, transforms into:

mOJ DQDQ SAMYH ^ESTNYH PRAWIL, kOGDA NE W [UTKU ZANEMOG, oN UWAVATX SEBQ ZASTAWIL, i LU^[E WYDUMATX NE MOG.

...perhaps this is not very appealing aesthetically, but this text is still readable to Russian language natives. Hence, Cyrillic text encoded in KOI-8R, passed through an old 7-bit service will survive into transliterated, but still readable text.

Stripping 8th bit is automatically transposes any character from the second half of the (any) 8-bit ASCII table to the first one, into the same place (take a look at red arrow right of table). If the character has already been placed in the first half (i.e., it has been in standard 7-bit ASCII table), it’s not transposed.

Perhaps, transliterated text is still recoverable, if you’ll add 8th bit to the characters which were seems transliterated.

Drawback is obvious: Cyrillic characters allocated in KOI-8R table are not in the same sequence as in Russian/Bulgarian/Ukrainian/etc. alphabet, and this isn’t suitable for sorting, for example.

2.5 AND and OR as subtraction and addition

2.5.1 ZX Spectrum ROM text strings

Those who once investigated ZX Spectrum ROM internals, probably noticed that the last symbol of each text string is seemingly absent.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There are present, in fact.

Here is excerpt of ZX Spectrum 128K ROM disassembled:

<table>

</table>

(http://www.matthew-wilson.net/spectrum/rom/128_ROM0.html)

Last character has most significant bit set, which marks string end. Presumably, it was done to save some space? Old 8-bit computers have very tight environment.

Characters of all messages are always in standard 7-bit ASCII table, so it's guaranteed 7th bit is never used for characters.

To print such string, we must check MSB of each byte, and if it's set, we must clear it, then print character, and then stop. Here is a C example:

```c
unsigned char hw[] =
{
    'H',
    'e',
    'l',
    'l',
    'o'|0x80
};

void print_string()
{
    for (int i=0; ;i++)
    {
        if (hw[i]&0x80) // check MSB
        {
            // clear MSB
            // (in other words, clear all, but leave 7 lower bits intact)
            printf ("%c", hw[i] & 0x7F);
            // stop
        }
    }
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
break;
    }
    printf("%c", hw[i]);
  }
};
};

Now what is interesting, since 7th bit is the most significant bit (in byte), we can check it, set it and remove it using arithmetical operations instead of logical.

I can rewrite my C example:

```c
unsigned char hw[] =
{
    'H',
    'e',
    'l',
    'l',
    'o'+0x80
};

void print()
{
    for (int i=0; ;i++)
    {
        // hw[] must have 'unsigned char' type
        if (hw[i] >= 0x80) // check for MSB
            {
            printf("%c", hw[i]-0x80); // clear MSB
        // stop
            break;
        }
        printf("%c", hw[i]);
    }
};

By default, char is signed type in C/C++, so to compare it with variable like 0x80 (which is negative (-128) if treated as signed), we must treat each character in text message as unsigned.

Now if 7th bit is set, the number is always larger or equal to 0x80. If 7th bit is clear, the number is always smaller than 0x80.

Even more than that: if 7th bit is set, it can be cleared by subtracting 0x80, nothing else. If it’s not set beforehand, however, subtracting will destruct other bits.

Likewise, if 7th bit is clear, it’s possible to set it by adding 0x80. But if it’s set beforehand, addition operation will destruct some other bits.

In fact, this is valid for any bit. If the 4th bit is clear, you can set it just by adding 0x10: 0x100+0x10 = 0x110. If the 4th bit is set, you can clear it by subtracting 0x10: 0x1234-0x10 = 0x1224.

It works, because carry isn’t happened during addition/subtraction. It will, however, happen, if the bit is already set there before addition, or absent before subtraction.

Likewise, addition/subtraction can be replaced using OR/AND operation if two conditions are met: 1) you want to add/subtract by a number in form of 2^n; 2) this bit in source value is clear/set.

For example, addition of 0x20 is the same as ORing value with 0x20 under condition that this bit is clear before: 0x1204|0x20 = 0x1204+0x20 = 0x1224.

Subtraction of 0x20 is the same as ANDing value with 0x20 (0x....FFDF), but if this bit is set before: 0x1234&(~0x20) = 0x1234&0xFFDF = 0x1234-0x20 = 0x1214.

Again, it works because carry not happened when you add 2^n number and this bit isn’t set before.

This property of boolean algebra is important, worth understanding and keeping it in mind.

Another example in this book: 3.17.3 on page 544.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2.6 XOR (exclusive OR)

XOR is widely used when one needs just to flip specific bit(s). Indeed, the XOR operation applied with 1 effectively inverts a bit:

<table>
<thead>
<tr>
<th>input A</th>
<th>input B</th>
<th>output</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

And vice-versa, the XOR operation applied with 0 does nothing, i.e., it’s an idle operation. This is a very important property of the XOR operation and it’s highly recommended to memorize it.

2.6.1 Logical difference

In Cray-1 supercomputer (1976-1977) manual 20, you can find XOR instruction was called logical difference.

Indeed, XOR(a,b)=1 if a!=b.

2.6.2 Everyday speech

XOR operation present in common everyday speech. When someone asks “please buy apples or bananas”, this usually means “buy the first object or the second, but not both”—this is exactly exclusive OR, because logical OR would mean “both objects are also fine”.

Some people suggest “and/or” should be used in everyday speech to make emphasis that logical OR is used instead of exclusive OR: https://en.wikipedia.org/wiki/And/or.

2.6.3 Encryption

XOR is heavily used in both amateur (9.1 on page 899) and real encryption (at least in Feistel network). XOR is very useful here because: \( \text{cipher}_{\text{text}} = \text{plain}_{\text{text}} \oplus \text{key} \) and then: \( (\text{plain}_{\text{text}} \oplus \text{key}) \oplus \text{key} = \text{plain}_{\text{text}} \).

2.6.4 RAID4

RAID4 offers a very simple method to protect hard disks. For example, there are several disks \((D_1, D_2, D_3, \text{ etc.})\) and one parity disk \((P)\). Each bit/byte written to parity disk is calculated and written on-fly:

\[
P = D_1 \oplus D_2 \oplus D_3
\]

(2.1)

If any of disks is failed, for example, \(D_2\), it’s restored using the very same way:

\[
D_2 = D_1 \oplus P \oplus D_3
\]

(2.2)

If parity disk failed, it is restored using 2.1 way. If two of any disks are failed, then it wouldn’t be possible to restore both.

RAID5 is more advanced, but this XOR property is still exploited there.

That’s why RAID controllers has hardware “XOR accelerators” helping to XOR large chunks of written data on-fly. When computers get faster and faster, it now can be done at software level, using SIMD.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2.6.5 XOR swap algorithm

Hard to believe, but this code swaps values in EAX and EBX without aid of any other additional register or memory cell:

```
xor eax, ebx
xor ebx, eax
xor eax, ebx
```

Let’s find out, how it works. First, we will rewrite it to step aside from x86 assembly language:

```
X = X XOR Y
Y = Y XOR X
X = X XOR Y
```

What X and Y has at each step? Just keep in mind the simple rule: \((X \oplus Y) \oplus Y = X\) for any values of X and Y.

Let’s see, \(X\) after 1st step has \(X \oplus Y\); \(Y\) after 2nd step has \(Y \oplus (X \oplus Y) = X\); \(X\) after 3rd step has \((X \oplus Y) \oplus X = Y\). Hard to say if anyone should use this trick, but it servers as a good demonstration example of XOR properties.

Wikipedia article ([https://en.wikipedia.org/wiki/XOR_swap_algorithm](https://en.wikipedia.org/wiki/XOR_swap_algorithm)) has also yet another explanation: addition and subtraction operations can be used instead of XOR:

```
X = X + Y
Y = X - Y
X = X - Y
```

Let’s see: \(X\) after 1st step has \(X + Y\); \(Y\) after 2nd step has \(X + Y - Y = X\); \(X\) after 3rd step has \(X + Y - X = Y\).

2.6.6 XOR linked list

Doubly linked list is a list in which each element has link to the previous element and to the next one. Hence, it’s very easy to traverse list backwards or forward. \(\text{std::list}\) in C++ implements doubly linked list which also is examined in this book: [3.19.4 on page 573](#).

So each element has two pointers. Is it possible, perhaps in environment of small RAM footprint, to preserve all functionality with one pointer instead of two? Yes, if it a value of \(\text{prev} \oplus \text{next}\) will be stored in this memory cell, which is usually called “link”.

Maybe, we could say that address to the previous element is “encrypted” using address of next element and otherwise: next element address is “encrypted” using previous element address.

When we traverse this list forward, we always know address of the previous element, so we can “decrypt” this field and get address of the next element. Likewise, it’s possible to traverse this list backwards, “decrypting” this field using next element’s address.

But it’s not possible to find address of previous or next element of some specific element without knowing address of the first one.

Couple of things to complete this solution: first element will have address of next element without any XOR-ing, last element will have address of previous element without any XOR-ing.

Now let’s sum it up. This is example of doubly linked list of 5 elements. \(A_x\) is address of element.

<table>
<thead>
<tr>
<th>address</th>
<th>link field contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>(A_0)</td>
<td>(A_1)</td>
</tr>
<tr>
<td>(A_1)</td>
<td>(A_0 \oplus A_2)</td>
</tr>
<tr>
<td>(A_2)</td>
<td>(A_1 \oplus A_3)</td>
</tr>
<tr>
<td>(A_3)</td>
<td>(A_2 \oplus A_4)</td>
</tr>
<tr>
<td>(A_4)</td>
<td>(A_3)</td>
</tr>
</tbody>
</table>

And again, hard to say if anyone should use this tricky hacks, but this is also a good demonstration of XOR properties. As with XOR swap algorithm, Wikipedia article about it also offers way to use addition or subtraction instead of XOR: [https://en.wikipedia.org/wiki/XOR_linked_list](https://en.wikipedia.org/wiki/XOR_linked_list).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2.6.7 Switching value trick

... found in Jorg Arndt — Matters Computational / Ideas, Algorithms, Source Code 21.

You want a variable to be switching between 123 and 456. You may write something like:

```c
if (a==123)
a=456;
else
 a=123;
```

But this can be done using a single operation:

```c
#include <stdio.h>

int main()
{
    int a=123;
    #define C 123^456

    a=a^C;
    printf ("%d\n", a);
    a=a^C;
    printf ("%d\n", a);
    a=a^C;
    printf ("%d\n", a);
}
```

It works because $123 \oplus 123 \oplus 456 = 0 \oplus 456 = 456$ and $456 \oplus 123 \oplus 456 \oplus 123 = 0 \oplus 123 = 123$.

One can argue, worth it using or not, especially keeping in mind code readability. But this is yet another demonstration of XOR properties.

2.6.8 Zobrist hashing / tabulation hashing

If you work on a chess engine, you traverse a game tree many times per second, and often, you can encounter the same position, which has already been processed.

So you have to use a method to store already calculated positions somewhere. But chess position can require a lot of memory, and a hash function would be used instead.

Here is a way to compress a chess position into 64-bit value, called Zobrist hashing:

```c
// we have 8*8 board and 12 pieces (6 for white side and 6 for black)
uint64_t table[12][8][8]; // filled with random values

int position[8][8]; // for each square on board. 0 - no piece. 1..12 - piece

uint64_t hash;

for (int row=0; row<8; row++)
    for (int col=0; col<8; col++)
    {
        int piece=position[row][col];
        if (piece!=0)
            hash=hash^table[piece][row][col];
    }
return hash;
```

Now the most interesting part: if the next (modified) chess position differs only by one (moved) piece, you don’t need to recalculate hash for the whole position, all you need is:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2.6.9 By the way

The usual OR also sometimes called inclusive OR (or even IOR), as opposed to exclusive OR. One place is operator Python’s library: it’s called operator.ior here.

2.6.10 AND/OR/XOR as MOV

OR reg, 0xFFFFFFFF sets all bits to 1, hence, no matter what has been in register before, it will be set to −1. OR reg, -1 is shorter than MOV reg, -1, so MSVC uses OR instead the latter, for example: 3.16.1 on page 534.

Likewise, AND reg, 0 always resets all bits, hence, it acts like MOV reg, 0.

XOR reg, reg, no matter what has been in register beforehand, resets all bits, and also acts like MOV reg, 0.

2.7 Population count

POPCNT instruction is population count (AKA Hamming weight). It just counts number of bits set in an input value.

As a side effect, POPCNT instruction (or operation) can be used to determine, if the value has $2^n$ form. Since, $2^n$ number always has just one single bit, POPCNT’s result will always be just 1.

For example, I once wrote a base64 strings scanner for hunting something interesting in binary files22. And there is a lot of garbage and false positives, so I add an option to filter out data blocks which has size of $2^n$ bytes (i.e., 256 bytes, 512, 1024, etc.). The size of block is checked just like this:

```c
if (popcnt(size)==1)
  // OK
...
```

The instruction is also known as “NSA23 instruction” due to rumors:

This branch of cryptography is fast-paced and very politically charged. Most designs are secret; a majority of military encryptions systems in use today are based on LFSRs. In fact, most Cray computers (Cray 1, Cray X-MP, Cray Y-MP) have a rather curious instruction generally known as “population count.” It counts the 1 bits in a register and can be used both to efficiently calculate the Hamming distance between two binary words and to implement a vectorized version of a LFSR. I’ve heard this called the canonical NSA instruction, demanded by almost all computer contracts.

[Bruce Schneier, Applied Cryptography, (John Wiley & Sons, 1994)]

2.8 Endianness

The endianness is a way of representing values in memory.

https://github.com/DennisYurichev/base64scanner

National Security Agency

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
2.8.1 Big-endian

The 0x12345678 value is represented in memory as:

<table>
<thead>
<tr>
<th>address in memory</th>
<th>byte value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0</td>
<td>0x12</td>
</tr>
<tr>
<td>+1</td>
<td>0x34</td>
</tr>
<tr>
<td>+2</td>
<td>0x56</td>
</tr>
<tr>
<td>+3</td>
<td>0x78</td>
</tr>
</tbody>
</table>

Big-endian CPUs include Motorola 68k, IBM POWER.

2.8.2 Little-endian

The 0x12345678 value is represented in memory as:

<table>
<thead>
<tr>
<th>address in memory</th>
<th>byte value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0</td>
<td>0x78</td>
</tr>
<tr>
<td>+1</td>
<td>0x56</td>
</tr>
<tr>
<td>+2</td>
<td>0x34</td>
</tr>
<tr>
<td>+3</td>
<td>0x12</td>
</tr>
</tbody>
</table>

Little-endian CPUs include Intel x86. One important example of little-endian using in this book is: ?? on page ??.

2.8.3 Example

Let’s take big-endian MIPS Linux installed and ready in QEMU 24.

And let’s compile this simple example:

```c
#include <stdio.h>

int main()
{
    int v;
    v=123;
    printf("%02X %02X %02X %02X\n",
           *(char*)&v,
           *((char*)&v)+1,
           *((char*)&v)+2,
           *((char*)&v)+3);
}
```

After running it we get:

```
root@debian-mips:~# ./a.out
00 00 00 7B
```

That is it. 0x7B is 123 in decimal. In little-endian architectures, 7B is the first byte (you can check on x86 or x86-64), but here it is the last one, because the highest byte goes first.

That’s why there are separate Linux distributions for MIPS (“mips” (big-endian) and “mipsel” (little-endian)). It is impossible for a binary compiled for one endianness to work on an OS with different endianness.

There is another example of MIPS big-endianess in this book: 1.30.4 on page 368.

2.8.4 Bi-endian

CPUs that may switch between endianness are ARM, PowerPC, SPARC, MIPS, IA6425, etc.

2.8.5 Converting data

The BSWAP instruction can be used for conversion.

TCP/IP network data packets use the big-endian conventions, so that is why a program working on a little-endian architecture has to convert the values. The `htonl()` and `htons()` functions are usually used.

In TCP/IP, big-endian is also called “network byte order”, while byte order on the computer “host byte order”. “host byte order” is little-endian on Intel x86 and other little-endian architectures, but it is big-endian on IBM POWER, so `htonl()` and `htons()` don’t shuffle any bytes on the latter.

2.9 Memory

There are 3 main types of memory:

- Global memory AKA “static memory allocation”. No need to allocate explicitly, the allocation is performed just by declaring variables/arrays globally. These are global variables, residing in the data or constant segments. They are available globally (hence, considered as an anti-pattern). Not convenient for buffers/arrays, because they must have a fixed size. Buffer overflows that occur here usually overwrite variables or buffers residing next to them in memory. There’s an example in this book: 1.12.3 on page 76.

- Stack AKA “allocate on stack”. The allocation is performed just by declaring variables/arrays locally in the function. These are usually local variables for the function. Sometimes these local variable are also available to descending functions (to callee functions, if caller passes a pointer to a variable to the callee to be executed). Allocation and deallocation are very fast, it just SP needs to be shifted. But they’re also not convenient for buffers/arrays, because the buffer size has to be fixed, unless `alloca()` (1.9.2 on page 34) (or a variable-length array) is used. Buffer overflows usually overwrite important stack structures: 1.26.2 on page 275.

- Heap AKA “dynamic memory allocation”. Allocation/deallocation is performed by calling `malloc()/free()` or new/delete in C++. This is the most convenient method: the block size may be set at runtime.

Resizing is possible (using realloc()), but can be slow. This is the slowest way to allocate memory: the memory allocator must support and update all control structures while allocating and deallocating. Buffer overflows usually overwrite these structures. Heap allocations are also source of memory leak problems: each memory block has to be deallocated explicitly, but one may forget about it, or do it incorrectly.

Another problem is the “use after free”—using a memory block after `free()` has been called on it, which is very dangerous.

Example in this book: 1.30.2 on page 351.

2.10 CPU

2.10.1 Branch predictors

Some latest compilers try to get rid of conditional jump instructions. Examples in this book are: 1.18.1 on page 135, 1.18.3 on page 143, 1.28.5 on page 333.

This is because the branch predictor is not always perfect, so the compilers try to do without conditional jumps, if possible.

Conditional instructions in ARM (like ADRcc) are one way, another one is the CMOVcc x86 instruction.
2.10.2 Data dependencies

Modern CPUs are able to execute instructions simultaneously (OOE\textsuperscript{26}), but in order to do so, the results of one instruction in a group must not influence the execution of others. Hence, the compiler endeavors to use instructions with minimal influence on the CPU state.

That’s why the LEA instruction is so popular, because it does not modify CPU flags, while other arithmetic instructions does.

2.11 Hash functions

A very simple example is CRC32, an algorithm that provides “stronger” checksum for integrity checking purposes. It is impossible to restore the original text from the hash value, it has much less information: But CRC32 is not cryptographically secure: it is known how to alter a text in a way that the resulting CRC32 hash value will be the one we need. Cryptographic hash functions are protected from this.

MD5, SHA1, etc. are such functions and they are widely used to hash user passwords in order to store them in a database. Indeed: an Internet forum database may not contain user passwords (a stolen database can compromise all users’ passwords) but only hashes (so a cracker can’t reveal the passwords). Besides, an Internet forum engine does not need to know your password exactly, it needs only to check if its hash is the same as the one in the database, and give you access if they match. One of the simplest password cracking methods is just to try hashing all possible passwords in order to see which matches the resulting value that we need. Other methods are much more complex.

2.11.1 How do one-way functions work?

A one-way function is a function which is able to transform one value into another, while it is impossible (or very hard) to reverse it. Some people have difficulties while understanding how this is possible at all. Here is a simple demonstration.

We have a vector of 10 numbers in range 0..9, each is present only once, for example:

```
4 6 0 1 3 5 7 8 9 2
```

The algorithm for the simplest possible one-way function is:

- take the number at zeroth position (4 in our case);
- take the number at first position (6 in our case);
- swap numbers at positions of 4 and 6.

Let’s mark the numbers at positions 4 and 6:

```
4 6 0 1 3 5 7 8 9 2
^ ^
```

Let’s swap them and we get this result:

```
4 6 0 1 7 5 3 8 9 2
```

While looking at the result, and even if we know the algorithm, we can’t know unambiguously the initial state, because the first two numbers could be 0 and/or 1, and then they could participate in the swapping procedure.

This is an utterly simplified example for demonstration. Real one-way functions are much more complex.

\textsuperscript{26}Out-of-Order Execution

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Chapter 3

Slightly more advanced examples

3.1 Double negation

A popular way\(^1\) to convert non-zero value into 1 (or boolean \textit{true}) and zero value into 0 (or boolean \textit{false}) is `!!statement`:

```c
int convert_to_bool(int a)
{
    return !!a;
}
```

Optimizing GCC 5.4 x86:

```assembly
convert_to_bool:
    mov edx, DWORD PTR [esp+4]
    xor eax, eax
    test edx, edx
    setne al
    ret
```

XOR always clears return value in EAX, even in case if SETNE will not trigger. I.e., XOR sets default return value to zero.

If the input value is not equal to zero (-NE suffix in SET instruction), 1 is set to AL, otherwise AL isn’t touched.

Why SETNE operates on low 8-bit part of EAX register? Because the matter is just in the last bit (0 or 1), while other bits are cleared by XOR.

Therefore, that C/C++ code could be rewritten like this:

```c
int convert_to_bool(int a)
{
    if (a!=0) return 1;
    else return 0;
}
```

...or even:

```c
int convert_to_bool(int a)
{
    if (a) return 1;
    else return 0;
}
```

Compilers targeting CPUs lacking instruction similar to SET, in this case, generates branching instructions, etc.

\(^1\)This way is also controversial, because it leads to hard-to-read code
3.2 const correctness

This is undeservedly underused feature of many programming languages. Read here about its importance: 1, 2.

Ideally, everything you don’t modify should have const modifier.

Interestingly, how const correctness is implemented at low level. There are no runtime checks of local const variables and function arguments (only compile-time checks). But global variables of such a type are to be allocated in read-only data segments.

This is example is to be crashed, because if compiled by MSVC for win32, the a global variable is allocated in .rdata read-only segment:

```c
const a=123;
void f(int *i)
{
    *i=11; // crash
};
int main()
{
    f(&a);
    return a;
};
```

Anonymous (not linked to a variable name) C strings also have const char* type. You can’t modify them:

```c
#define include <string.h>
#define include <stdio.h>

void alter_string(char *s)
{
    strcpy (s, "Goodbye!");
    printf ("Result: %s\n", s);
};
int main()
{
    alter_string ("Hello, world!\n");
};
```

This code will crash on Linux (“segmentation fault”) and on Windows if compiled by MinGW.

GCC for Linux places all text strings info .rodata data segment, which is explicitly read-only (“read only data”):

```
$ objdump -s 1
...
Contents of section .rodata:
 400600 01000200 52657375 6c743a20 25730a00 ....Result: %s..
 400610 48656c6c 6f2c2077 6f726c64 210a00 Hello, world!..
```

When the alter_string() function tries to write there, exception occurred.

Things are different in the code generated by MSVC, strings are located in .data segment, which has no READONLY flag. MSVC’s developers misstep?

```
C:\...>objdump -s 1.exe
...
Contents of section .data:
 40b000 476f6f64 62796521 00000000 52657375 6c743a20 25730a00 ....Result: %s..
 40b010 6c743a20 25730a77 6f726c64 210a00 Hello, world!..
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
C:\...>objdump -x 1.exe

</tbody>
</table>

However, MinGW hasn't this fault and allocates text strings in .rdata segment.

### 3.2.1 Overlapping const strings

The fact that an anonymous C-string has `const` type (1.5.1 on page 9), and that C-strings allocated in constants segment are guaranteed to be immutable, has an interesting consequence: the compiler may use a specific part of the string.

Let's try this example:

```c
#include <stdio.h>

int f1()
{
    printf ("world\n");
}

int f2()
{
    printf ("hello world\n");
}

int main()
{
    f1();
    f2();
}
```

Common C/C++-compilers (including MSVC) allocate two strings, but let's see what GCC 4.8.1 does:

```
Listing 3.1: GCC 4.8.1 + IDA listing

f1 proc near
    s    = dword ptr -1Ch
sub    esp, 1Ch
mov    [esp+1Ch+s], offset s ; "world\n"
call   _puts
add    esp, 1Ch
retn
f1 endp

f2 proc near
    s    = dword ptr -1Ch
sub    esp, 1Ch
mov    [esp+1Ch+s], offset aHello ; "hello 
ncall   _puts
add    esp, 1Ch
retn
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Indeed: when we print the “hello world” string these two words are positioned in memory adjacently and `puts()` called from `f2()` function is not aware that this string is divided. In fact, it’s not divided; it’s divided only virtually, in this listing.

When `puts()` is called from `f1()`, it uses the “world” string plus a zero byte. `puts()` is not aware that there is something before this string!

This clever trick is often used by at least GCC and can save some memory. This is close to string interning.

Another related example is here: 3.3.

### 3.3 `strstr()` example

Let’s back to the fact that GCC sometimes can use part of string: 3.2.1 on the previous page.

The `strstr()` C/C++ standard library function is used to find any occurrence in a string. This is what we will do:

```c
#include <string.h>
#include <stdio.h>

int main()
{
  char *s="Hello, world!";
  char *w=strstr(s, "world");
  printf ("%p, [%s]\n", s, s);
  printf ("%p, [%s]\n", w, w);
}
```

The output is:

```
0x8048530, [Hello, world!]
0x8048537, [world!]
```

The difference between the address of the original string and the address of the substring that `strstr()` has returned is 7. Indeed, “Hello,” string has length of 7 characters.

The `printf()` function during second call has no idea there are some other characters before the passed string and it prints characters from the middle of original string till the end (marked by zero byte).

### 3.4 Temperature converting

Another very popular example in programming books for beginners is a small program that converts Fahrenheit temperature to Celsius or back.

\[
C = \frac{5 \cdot (F - 32)}{9}
\]

We can also add simple error handling: 1) we must check if the user has entered a correct number; 2) we must check if the Celsius temperature is not below \(-273\) (which is below absolute zero, as we may recall from school physics lessons).

The `exit()` function terminates the program instantly, without returning to the caller function.
#include <stdio.h>
#include <stdlib.h>

int main()
{
    int celsius, fahr;
    printf ("Enter temperature in Fahrenheit:\n");
    if (scanf ("%d", &fahr)!=1)
    {
        printf ("Error while parsing your input\n");
        exit(0);
    }
    celsius = 5 * (fahr-32) / 9;
    if (celsius<-273)
    {
        printf ("Error: incorrect temperature!\n");
        exit(0);
    }
    printf ("Celsius: %d\n", celsius);
}

Optimizing MSVC 2012 x86

Listing 3.2: Optimizing MSVC 2012 x86

$SG4228 DB 'Enter temperature in Fahrenheit:', 0aH, 00H
$SG4230 DB '%d', 00H
$SG4231 DB 'Error while parsing your input', 0aH, 00H
$SG4233 DB 'Error: incorrect temperature!', 0aH, 00H
$SG4234 DB 'Celsius: %d', 0aH, 00H

_fahr$ = -4 ; size = 4
_main PROC
    push ecx
    push esi
    mov esi, DWORD PTR _imp__printf
    push OFFSET $SG4228 ; 'Enter temperature in Fahrenheit:'
    call esi ; call printf()
    lea eax, DWORD PTR _fahr$[esp+12]
    push eax
    push OFFSET $SG4230 ; '%d'
    call DWORD PTR _imp__scanf
    add esp, 12
    cmp eax, 1
    je SHORT $LN2@main
    push OFFSET $SG4231 ; 'Error while parsing your input'
    call esi ; call printf()
    add esp, 4
    push 0
    call DWORD PTR _imp__exit
$LN9@main:
$LN2@main:
    mov eax, DWORD PTR _fahr$[esp+8]
    add eax, -32 ; fffffffe0H
    lea ecx, DWORD PTR [eax+eax*4]
    mov eax, 954437177 ; 38e38e39H
    imul ecx
    sar edx, 1
    mov eax, edx
    shr eax, 31 ; 0000001fH
    add eax, edx
    cmp eax, -273 ; fffffeefH
    jge SHORT $LN1@main
    push OFFSET $SG4233 ; 'Error: incorrect temperature!'
What we can say about it:

- The address of printf() is first loaded in the ESI register, so the subsequent printf() calls are done just by the CALL ESI instruction. It's a very popular compiler technique, possible if several consequent calls to the same function are present in the code, and/or if there is a free register which can be used for this.

- We see the ADD EAX, -32 instruction at the place where 32 has to be subtracted from the value. EAX = EAX + (-32) is equivalent to EAX = EAX - 32 and somehow, the compiler decided to use ADD instead of SUB. Maybe it's worth it; it's hard to be sure.

- The LEA instruction is used when the value is to be multiplied by 5: lea ecx, DWORD PTR [eax+eax*4]. Yes, i+i*4 is equivalent to i*5 and LEA works faster than IMUL.

- The division by multiplication trick (3.10 on page 504) is also used here.

- main() returns 0 if we don’t have return 0 at its end. The C99 standard tells us [ISO/IEC 9899:TC3 (C C99 standard), (2007)5.1.2.2.3] that main() will return 0 in case the return statement is missing. This rule works only for the main() function.

  Though, MSVC doesn’t officially support C99, but maybe it support it partially?

### Optimizing MSVC 2012 x64

The code is almost the same, but we can find INT 3 instructions after each exit() call.

```
xor  ecx, ecx
call  QWORD PTR __imp_exit
int  3
```

INT 3 is a debugger breakpoint.

It is known that exit() is one of the functions which can never return \(^2\), so if it does, something really odd has happened and it’s time to load the debugger.

### 3.4.2 Floating-point values

```c
#include <stdio.h>
#include <stdlib.h>

int main()
{
    double celsius, fahr;
    printf("Enter temperature in Fahrenheit:\n");
    if (scanf("%lf", &fahr)!=1)
    {
```

\(^2\)another popular one is longjmp()
printf ("Error while parsing your input\n");
exit(0);

celsius = 5 * (fahr-32) / 9;
if (celsius<-273)
{
    printf ("Error: incorrect temperature!\n");
    exit(0);
};
printf ("Celsius: %lf\n", celsius);

MSVC 2010 x86 uses FPU instructions...

Listing 3.3: Optimizing MSVC 2010 x86

$SG4038 DB 'Enter temperature in Fahrenheit:', 0AH, 00H

  push 0
  call DWORD PTR __imp__exit

$LN10@main:
$LN1@main:
  sub esp, 8
  movsd QWORD PTR [esp], xmm1
  push OFFSET $SG4234 ; 'Celsius: %lf'
  call esi ; call printf()
  add esp, 12
  ; return 0 - by C99 standard
  xor eax, eax
  pop esi
  add esp, 8
  ret 0

$LN8@main:
__main ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Of course, SIMD instructions are available in x86 mode, including those working with floating point numbers.

It’s somewhat easier to use them for calculations, so the new Microsoft compiler uses them.

We can also see that the \(-273\) value is loaded into XMM0 register too early. And that’s OK, because the compiler may emit instructions not in the order they are in the source code.

### 3.5 Fibonacci numbers

Another widespread example used in programming textbooks is a recursive function that generates the Fibonacci numbers\(^3\). The sequence is very simple: each consecutive number is the sum of the previous two. The first two numbers are 0 and 1, or 1 and 1.

The sequence starts like this:

\[
0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181... 
\]

#### 3.5.1 Example #1

The implementation is simple. This program generates the sequence until 21.

```c
#include <stdio.h>

void fib (int a, int b, int limit)
{
    printf("%d\n", a+b);
    if (a+b > limit)
        return;
    fib (b, a+b, limit);
}

int main()
{
    printf("0\n1\n1\n");
    fib (1, 1, 20);
}
```

Listing 3.5: MSVC 2010 x86

```
.a$ = 8 ; size = 4
_b$ = 12 ; size = 4
__limit$ = 16 ; size = 4

_fib PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _a$[ebp]
    add eax, DWORD PTR _b$[ebp]
    push eax
    push OFFSET $SG2643
    call DWORD PTR __imp__printf
    add esp, 8
    mov ecx, DWORD PTR _a$[ebp]
    add ecx, DWORD PTR __limit$[ebp]
    cmp ecx, DWORD PTR __limit$[ebp]
    jle SHORT $LN1@fib
    jmp SHORT $LN2@fib
$LN1@fib:
    mov edx, DWORD PTR __limit$[ebp]
    push edx
    mov eax, DWORD PTR _a$[ebp]
    add eax, DWORD PTR _b$[ebp]
    push eax
    mov ecx, DWORD PTR _b$[ebp]
    push ecx
$LN2@fib:
```

</tr>
</tbody>
</table>

The function is recursive, hence stack looks like a “sandwich”.

We see that the limit argument is always the same (0x14 or 20), but the a and b arguments are different for each call.

There are also the RA-s and the saved EBP values. OllyDbg is able to determine the EBP-based frames, so it draws these brackets. The values inside each bracket make the stack frame, in other words, the stack area which each function incarnation uses as scratch space.

We can also say that each function incarnation must not access stack elements beyond the boundaries of its frame (excluding function arguments), although it’s technically possible.

It’s usually true, unless the function has bugs.

Each saved EBP value is the address of the previous stack frame: this is the reason why some debuggers can easily divide the stack in frames and dump each function’s arguments.

As we see here, each function incarnation prepares the arguments for the next function call.

At the end we see the 3 arguments for main(). argc is 1 (yes, indeed, we have ran the program without command-line arguments).

This easily to lead to a stack overflow: just remove (or comment out) the limit check and it will crash with exception 0xC00000FD (stack overflow.)

### 3.5.2 Example #2

My function has some redundancy, so let’s add a new local variable next and replace all “a+b” with it:

---

4The way, it’s possible to select several entries in OllyDbg and copy them to the clipboard (Ctrl-C). That’s what was done by author for this example.

5i.e., it calls itself
```c
#include <stdio.h>

void fib (int a, int b, int limit)
{
    int next = a + b;
    printf ("%d\n", next);
    if (next > limit)
        return;
    fib (b, next, limit);
};

int main()
{
    printf ("0\n1\n1\n\n");
    fib (1, 1, 20);
};
```

This is the output of non-optimizing MSVC, so the `next` variable is actually allocated in the local stack:

```
Listing 3.6: MSVC 2010 x86

_next$ = -4 ; size = 4
_a$ = 8 ; size = 4
_b$ = 12 ; size = 4
_limit$ = 16 ; size = 4
_fib PROC
    push ebp
    mov ebp, esp
    push ecx
    mov eax, DWORD PTR _a$[ebp]
    add eax, DWORD PTR _b$[ebp]
    mov DWORD PTR _next$[ebp], eax
    mov ecx, DWORD PTR _next$[ebp]
    push ecx
    push OFFSET $SG2751 ; 'd'
    call DWORD PTR __imp__printf
    add esp, 8
    mov edx, DWORD PTR _next$[ebp]
    cmp edx, DWORD PTR _limits$[ebp]
    jle SHORT $LN1@fib
    jmp SHORT $LN2@fib
$LN1@fib:
    mov eax, DWORD PTR _limits$[ebp]
    push eax
    mov ecx, DWORD PTR _next$[ebp]
    push ecx
    mov edx, DWORD PTR _b$[ebp]
    push edx
    call _fib
    add esp, 12
$LN2@fib:
    mov esp, ebp
    pop ebp
    ret 0
_fib ENDP

_main PROC
    push ebp
    mov ebp, esp
    push OFFSET $SG2753 ; "0\n1\n1\n"
    call DWORD PTR __imp__printf
    add esp, 4
    push 20
    push 1
    push 1
    call _fib
    add esp, 12
    xor eax, eax
    pop ebp
    ret 0
_main ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let’s load it in OllyDbg once again:

Figure 3.2: OllyDbg: last call of f()

Now the next variable is present in each frame.
Let’s investigate the stack more closely. The author has again added his comments:

</tbody>
</table>

Here we see it: the next value is calculated in each function incarnation, then passed as argument \( b \) to the next incarnation.

### 3.5.3 Summary

Recursive functions are aesthetically nice, but technically may degrade performance because of their heavy stack usage. Everyone who writes performance critical code probably should avoid recursion. For example, the author of this book once wrote a function to seek a particular node in a binary tree. As a recursive function it looked quite stylish but since additional time was spent at each function call for the prologue/epilogue, it was working a couple of times slower than an iterative (recursion-free) implementation.

By the way, that is the reason that some functional PL\(^6\) compilers (where recursion is used heavily) use tail call. We talk about tail call when a function has only one single call to itself located at the end of it, like:

```plaintext
;; factorial : number -> number
;; to calculate the product of all positive
;; integers less than or equal to n.
(define (factorial n)
  (if (= n 1)
      1
      (begin (factorial (- n 1)) (* n n))
)
```

\(^6\)LISP, Python, Lua, etc.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Tail call is important because compiler can rework this code easily into iterative one, to get rid of recursion.

### 3.6 CRC32 calculation example

This is a very popular table-based CRC32 hash calculation technique.

```c
/* By Bob Jenkins, (c) 2006, Public Domain */

#include <stdio.h>
#include <stdint.h>
#include <string.h>

typedef unsigned long ub4;

typedef unsigned char ub1;

static const ub4 crctab[256] = {

```
void build_table()
{
    ub4 i, j;
    for (i=0; i<256; ++i) {
        j = i;
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        printf("0x%.8lx, ", j);
        if (i%6 == 5) printf("\n");
    }
}

/* the hash function */
ub4 crc(const void *key, ub4 len, ub4 hash)
{
    ub4 i;
    const ub1 *k = key;
    for (hash=len, i=0; i<len; ++i)
    {
        hash = (hash >> 8) ^ crctab[(hash & 0xff) ^ k[i]];
        return hash;
    }
}

We are interested in the crc() function only. By the way, pay attention to the two loop initializers in the for() statement: hash=len, i=0. The C/C++ standard allows this, of course. The emitted code will contain two operations in the loop initialization part instead of one.

Let’s compile it in MSVC with optimization (/Ox). For the sake of brevity, only the crc() function is listed here, with my comments.

```assembly
 mov edx, DWORD PTR _len$[esp-4]  ; size = 4
 xor ecx, ecx ; i will be stored in ECX
 mov eax, edx
test edx, edx
jbe SHORT $LN1@crc
push ebx
push esi
mov esi, DWORD PTR _key$[esp+4] ; ESI = key
push edi

$LL3@crc:

; work with bytes using only 32-bit registers. byte from address key+i we store into EDI
movzx edi, BYTE PTR [ecx+esi]
 mov ebx, eax ; EBX = (hash = len)
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
and ebx, 255 ; EBX = hash & 0xff

; XOR EDI, EBX (EDI=EDI^EBX) - this operation uses all 32 bits of each register
; but other bits (8-31) are cleared all time, so it is OK
; these are cleared because, as for EDI, it was done by MOVZX instruction above
; high bits of EBX was cleared by AND EBX, 255 instruction above (255 = 0xff)
ex

; EAX=EAX>>8; bits 24:31 taken from nowhere will be cleared
shr eax, 8

; EAX=EAX^crctab[EDI*4] - choose EDI-th element from crctab[] table
xor eax, DWORD PTR _crctab[edi*4]
inc ecx ; i++
cmp ecx, edx ; i<len ?
jb SHORT $LL3@crc ; yes
pop edi
pop esi
pop ebx
$LN1@crc:
ret 0
_crc ENDP

Let's try the same in GCC 4.4.1 with -O3 option:

public crc
crc proc near
key = dword ptr 8
hash = dword ptr 0Ch
push ebp
xor edx, edx
mov ebp, esp
push esi
mov esi, [ebp+key]
push ebx
mov ebx, [ebp+hash]
test ebx, ebx
jz short loc_80484D3
nop ; padding
lea esi, [esi+0] ; padding; works as NOP (ESI does not change here)

loc_80484B8:
mov ecx, eax ; save previous state of hash to ECX
xor al, [esi+edx] ; AL=*(key+i)
add edx, 1 ; i++
shr ecx, 8 ; ECX=hash>>8
movzx eax, al ; EAX=*(key+i)
mov eax, dword ptr ds:crctab[eax*4] ; EAX=crctab[EAX]
xor eax, ecx ; hash=EAX^ECX
cmp ebx, edx
ja short loc_80484B8

loc_80484D3:
pop ebx
pop esi
pop ebp
retn
crc endp

GCC has aligned the loop start on a 8-byte boundary by adding NOP and lea esi, [esi+0] (that is an idle operation too). Read more about it in npad section (.1.7 on page 1011).
As we know, a TCP/IP address (IPv4) consists of four numbers in the 0...255 range, i.e., four bytes. Four bytes can be fit in a 32-bit variable easily, so an IPv4 host address, network mask or network address can all be 32-bit integers.

From the user’s point of view, the network mask is defined as four numbers and is formatted like 255.255.255.0 or so, but network engineers (sysadmins) use a more compact notation (CIDR\(^8\)), like “/8”, “/16”, etc.

This notation just defines the number of bits the mask has, starting at the MSB.

| /8   | 16777216 | 16777214 | 255.255.255.0 | 0xff000000 | class A network

Here is a small example, which calculates the network address by applying the network mask to the host address.

```c
#include <stdio.h>
#include <stdint.h>

uint32_t form_IP (uint8_t ip1, uint8_t ip2, uint8_t ip3, uint8_t ip4)
{
    return (ip1<<24) | (ip2<<16) | (ip3<<8) | ip4;
};

void print_as_IP (uint32_t a)
{
    printf (“%d.%d.%d.%d
”,
        (a>>24)&0xFF,
        (a>>16)&0xFF,
        (a>>8)&0xFF,
        (a)&0xFF);
};

// bit=31..0
uint32_t set_bit (uint32_t input, int bit)
{
    return input=input|(1<<bit);
};

uint32_t form_netmask (uint8_t netmask_bits)
{
    uint32_t netmask=0;
    uint8_t i;

    for (i=0; i<netmask_bits; i++)
        netmask=set_bit(netmask, 31-i);
    return netmask;
};

void calc_network_address (uint8_t ip1, uint8_t ip2, uint8_t ip3, uint8_t ip4, uint8_t netmask_bits)
{
```

\(^8\)Classless Inter-Domain Routing

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
uint32_t netmask = form_netmask(netmask_bits);
uint32_t ip = form_IP(ip1, ip2, ip3, ip4);
uint32_t netw_adr;

printf ("netmask=");
print_as_IP (netmask);

netw_adr = ip & netmask;

printf ("network address=");
print_as_IP (netw_adr);

int main()
{
calc_network_address (10, 1, 2, 4, 24); // 10.1.2.4, /24
calc_network_address (10, 1, 2, 4, 8); // 10.1.2.4, /8
calc_network_address (10, 1, 2, 4, 25); // 10.1.2.4, /25
calc_network_address (10, 1, 2, 64, 26); // 10.1.2.4, /26
}

3.7.1 calc_network_address()

calc_network_address() function is simplest one: it just ANDs the host address with the network mask, resulting in the network address.

3.7.2 form_IP()

The form_IP() function just puts all 4 bytes into a 32-bit value.

At line 22 we see the most important AND—here the network address is calculated.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
• Take the fourth (lowest) byte, apply OR operation to this byte and return the value. The return value contain the 4th byte now.

• Take the third byte, shift it left by 8 bits. You’ll get a value like 0x0000bb00 where bb is your third byte. Apply the OR operation to the resulting value and returning value. The return value has contained 0x000000aa so far, so ORing the values will produce a value like 0x0000bb00.

• Take the second byte, shift it left by 16 bits. You’ll get a value like 0x0000cc00, where cc is your second byte. Apply the OR operation to the resulting value and returning value. The return value has contained 0x000000bb00 so far, so ORing the values will produce a value like 0x0000cc00.

• Take the first byte, shift it left by 24 bits. You’ll get a value like 0xdd000000, where dd is your first byte. Apply the OR operation to the resulting value and returning value. The return value has contained 0x000000cc00 so far, so ORing the values will produce a value like 0xdd000000.

And this is how it’s done by non-optimizing MSVC 2012:

Listing 3.9: Non-optimizing MSVC 2012

; denote ip1 as "dd", ip2 as "cc", ip3 as "bb", ip4 as "aa".
_ip1$ = 8 ; size = 1
_ip2$ = 12 ; size = 1
_ip3$ = 16 ; size = 1
_ip4$ = 20 ; size = 1
_form_IP PROC
    push    ebp
    mov     ebp, esp
    movzx   eax, BYTE PTR _ip1$[ebp]
          ; EAX=000000dd
    shl     eax, 24
          ; EAX=dd000000
    movzx   ecx, BYTE PTR _ip2$[ebp]
          ; ECX=000000cc
    shl     ecx, 16
          ; ECX=00cc0000
    or      eax, ecx
          ; EAX=ddcc0000
    movzx   edx, BYTE PTR _ip3$[ebp]
          ; EDX=000000bb
    shl     edx, 8
          ; EDX=0000bb00
    or      eax, edx
          ; EAX=ddccbb00
    movzx   ecx, BYTE PTR _ip4$[ebp]
          ; ECX=000000aa
    or      eax, ecx
          ; EAX=ddccbbaa
    pop     ebp
    ret 0
_form_IP ENDP

Well, the order is different, but, of course, the order of the operations doesn’t matter.

Optimizing MSVC 2012 does essentially the same, but in a different way:

Listing 3.10: Optimizing MSVC 2012 /Ob0

; denote ip1 as "dd", ip2 as "cc", ip3 as "bb", ip4 as "aa".
_ip1$ = 8 ; size = 1
_ip2$ = 12 ; size = 1
_ip3$ = 16 ; size = 1
_ip4$ = 20 ; size = 1
_form_IP PROC
    movzx   eax, BYTE PTR _ip1$[esp-4]
          ; EAX=000000dd
    movzx   ecx, BYTE PTR _ip2$[esp-4]
          ; ECX=000000cc
    shl     eax, 8
          ; EAX=0000dd00
    or      eax, ecx
          ; EAX=0000ddcc
    movzx   ecx, BYTE PTR _ip3$[esp-4]

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We could say that each byte is written to the lowest 8 bits of the return value, and then the return value is shifted left by one byte at each step.

Repeat 4 times for each input byte.

That’s it! Unfortunately, there are probably no other ways to do it.

There are no popular CPUs or ISAs which has instruction for composing a value from bits or bytes.

It’s all usually done by bit shifting and ORing.

### 3.7.3 print_as_IP()

print_as_IP() does the inverse: splitting a 32-bit value into 4 bytes.

Slicing works somewhat simpler: just shift input value by 24, 16, 8 or 0 bits, take the bits from zeroth to seventh (lowest byte), and that’s it:

**Listing 3.11: Non-optimizing MSVC 2012**

```assembly
; size = 4
_print_as_IP PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    ; EAX=ddccbbaa
    and     eax, 255
    ; EAX=000000aa
    push    eax
    mov     ecx, DWORD PTR _a$[ebp]
    ; ECX=ddccbbaa
    shr     ecx, 8
    ; ECX=00ddccbb
    and     ecx, 255
    ; ECX=000000bb
    push    ecx
    mov     edx, DWORD PTR _a$[ebp]
    ; EDX=ddccbbaa
    shr     edx, 16
    ; EDX=0000ddcc
    and     edx, 255
    ; EDX=000000cc
    push    edx
    mov     eax, DWORD PTR _a$[ebp]
    ; EAX=ddccbbaa
    shr     eax, 24
    ; EAX=000000dd
    and     eax, 255 ; probably redundant instruction
    ; EAX=000000dd
    push    eax
    push    OFFSET $SG2973 ; '%d.%d.%d.%d'
call    DWORD PTR __imp__printf
    add     esp, 20
    pop     ebp
    ret     0
_print_as_IP ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Optimizing MSVC 2012 does almost the same, but without unnecessary reloading of the input value:

Listing 3.12: Optimizing MSVC 2012 /Ob0

```assembly
_a$ = 8 ; size = 4
_print_as_IP PROC
  mov  ecx, DWORD PTR _a$[esp-4]
  ; ECX=ddcbbbaa
  movzx eax, cl
  ; EAX=000000aa
  push eax
  mov  eax, ecx
  ; EAX=ddcbbbaa
  shr eax, 8
  ; EAX=000000bb
  and eax, 255
  ; EAX=000000bb
  push eax
  mov  eax, ecx
  ; EAX=ddcbbbaa
  shr eax, 16
  ; EAX=0000ddcc
  and eax, 255
  ; EAX=000000cc
  push eax
  mov  ecx=ddcbbbaa
  shr ecx, 24
  ; ECX=000000dd
  push ecx
  push OFFSET $SG3020 ; '%d.%d.%d.%d'
call DWORD PTR __imp__printf
add esp, 20
ret 0
_print_as_IP ENDP
```

3.7.4 form_netmask() and set_bit()

form_netmask() makes a network mask value from CIDR notation. Of course, it would be much effective to use here some kind of a precalculated table, but we consider it in this way intentionally, to demonstrate bit shifts.

We will also write a separate function set_bit(). It’s a not very good idea to create a function for such primitive operation, but it would be easy to understand how it all works.

Listing 3.13: Optimizing MSVC 2012 /Ob0

```assembly
_input$ = 8 ; size = 4
_bit$ = 12 ; size = 4
_set_bit PROC
  mov  ecx, DWORD PTR _bit$[esp-4]
  mov  eax, 1
  shl eax, cl
  or  eax, DWORD PTR _input$[esp-4]
ret 0
_set_bit ENDP

_netmask_bits$ = 8 ; size = 1
_form_netmask PROC
  push ebx
  push esi
  movzx esi, BYTE PTR _netmask_bits$[esp+4]
  xor ecx, ecx
  xor bl, bl
  test esi, esi
  jle SHORT $LN9@form_netma
  xor edx, edx
$LL3@form_netma:
  mov  eax, 31
  sub  eax, edx
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
push    eax
push    ecx
call    _set_bit
inc     bl
movzx   edx, bl
add     esp, 8
mov     ecx, eax
cmp     edx, esi
jl      SHORT $LL3@form_netma
.pop    esi
mov     eax, ecx
.pop    ebx
ret     0
_form_netmask ENDP

set_bit() is primitive: it just shift left 1 to number of bits we need and then ORs it with the “input” value.
form_netmask() has a loop: it will set as many bits (starting from the MSB) as passed in the netmask_bits argument.

3.7.5 Summary

That’s it! We run it and getting:

<table>
<thead>
<tr>
<th>netmask</th>
<th>network address</th>
</tr>
</thead>
<tbody>
<tr>
<td>255.255.255.0</td>
<td>10.1.2.0</td>
</tr>
<tr>
<td>255.0.0.0</td>
<td>10.0.0.0</td>
</tr>
<tr>
<td>255.255.255.128</td>
<td>10.1.2.0</td>
</tr>
<tr>
<td>255.255.255.192</td>
<td>10.1.2.64</td>
</tr>
</tbody>
</table>

3.8 Loops: several iterators

In most cases loops have only one iterator, but there could be several in the resulting code.

Here is a very simple example:

```c
#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t i;

    // copy from one array to another in some weird scheme
    for (i=0; i<cnt; i++)
        a1[i*3]=a2[i*7];
}
```

There are two multiplications at each iteration and they are costly operations. Can we optimize it somehow?

Yes, if we notice that both array indices are jumping on values that we can easily calculate without multiplication.

3.8.1 Three iterators

Listing 3.14: Optimizing MSVC 2013 x64

```
f   PROC
    ; RCX=a1
    ; RDX=a2
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now there are 3 iterators: the \texttt{cnt} variable and two indices, which are increased by 12 and 28 at each iteration. We can rewrite this code in C/C++:

```c
#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t i;
    size_t idx1=0; idx2=0;

    // copy from one array to another in some weird scheme
    for (i=0; i<cnt; i++)
    {
        a1[idx1]=a2[idx2];
        idx1+=3;
        idx2+=7;
    }
}
```

So, at the cost of updating 3 iterators at each iteration instead of one, we can remove two multiplication operations.

### 3.8.2 Two iterators

GCC 4.9 does even more, leaving only 2 iterators:

```assembly
; RDI=a1
; RSI=a2
; RDX=cnt
f:
    test rdx, rdx ; cnt==0? exit then
    je .L1
; calculate last element address in "a2" and leave it in RDX
    lea rax, [0+rdx*4]
    RAX=RDX*4=cnt*4
    sal rdx, 5
    RDX=RDX<<5=cnt*32
    sub rdx, rax
    RDX=RDX-RAX=cnt*32-cnt*4=cnt*28
    add rdx, rsi
    RDX=RDX+RSI=a2+cnt*28
    .L3:
        mov eax, DWORD PTR [rsi]
        add rsi, 28
        add rdi, 12
        mov DWORD PTR [rdi-12], eax
        cmp rsi, rdx
        jne .L3
    .L1:
        rep ret
```

(For statistics collecting purposes) if you've read this far, please click \url{here}. Thanks!
There is no counter variable any more: GCC concluded that it is not needed.

The last element of the a2 array is calculated before the loop begins (which is easy: $cnt \times 7$) and that’s how the loop is to be stopped: just iterate until the second index reaches this precalculated value.

You can read more about multiplication using shifts/additions/subtractions here: 1.24.1 on page 215.

This code can be rewritten into C/C++ like that:

```c
#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t idx1=0; idx2=0;
    size_t last_idx2=cnt*7;

    // copy from one array to another in some weird scheme
    for (;;) {
        a1[idx1]=a2[idx2];
        idx1+=3;
        idx2+=7;
        if (idx2==last_idx2)
            break;
    }
}
```

GCC (Linaro) 4.9 for ARM64 does the same, but it precalculates the last index of a1 instead of a2, which, of course has the same effect:

Listing 3.16: Optimizing GCC (Linaro) 4.9 ARM64

```asm
; X0=a1
; X1=a2
; X2=cnt
f:
    cbz x2, .L1 ; cnt==0? exit then
; calculate last element of "a1" array
    add x2, x2, x2, lsl 1
    X2=X2+X2<<1=X2+X2*2=X2*3
    mov x3, 0
    lsl x2, x2, 2
    X2=X2<<2=X2*4=X2*3*4=X2*12
.L3:
    ldr w4, [x1],28 ; load at X1, add 28 to X1 (post-increment)
    str w4, [x0,x3] ; store at X0+X3=a1+X3
    add x3, x3, 12 ; shift X3
    cmp x3, x2 ; end?
    bne .L3
.L1:
    ret
```

GCC 4.4.5 for MIPS does the same:

Listing 3.17: Optimizing GCC 4.4.5 for MIPS (IDA)

```asm
; $a0=a1
; $a1=a2
; $a2=cnt
f:
    beqz $a2, locret_24
; initialize counter (i) at 0:
    move $v0, $zero ; branch delay slot, NOP
loc_8:
; load 32-bit word at $a1
    lw $a3, 0($a1)
; increment counter (i):
    addiu $v0, 1
; check for finish (compare "i" in $v0 and "cnt" in $a2):
    sltu $v1, $v0, $a2
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.8.3 Intel C++ 2011 case

Compiler optimizations can also be weird, but nevertheless, still correct. Here is what the Intel C++ compiler 2011 does:

Listing 3.18: Optimizing Intel C++ 2011 x64

```assembly
f PROC
; parameter 1: rcx = a1
; parameter 2: rdx = a2
; parameter 3: r8 = cnt
.B1.1::
  test r8, r8
  jbe exit

.B1.2::
  cmp r8, 6
  jbe just_copy

.B1.3::
  cmp rcx, rdx
  jbe .B1.5

.B1.4::
  mov r10, r8
  mov r9, rcx
  shl r10, 5
  lea rax, QWORD PTR [r8*4]
  sub r9, rdx
  sub r10, rax
  cmp r9, r10
  jge just_copy2

.B1.5::
  cmp rdx, rcx
  jbe just_copy

.B1.6::
  mov r9, rdx
  lea rax, QWORD PTR [r8*8]
  sub r9, rcx
  lea r10, QWORD PTR [rax+r8*4]
  cmp r9, r10
  jl just_copy2

just_copy2::
; R8 = cnt
; RDX = a2
; RCX = a1
  xor r10d, r10d
  xor r9d, r9d
  xor eax, eax

.B1.8::
  mov r11d, DWORD PTR [rax+rdx]
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
First, there are some decisions taken, then one of the routines is executed.

Looks like it is a check if arrays intersect.

This is very well known way of optimizing memory block copy routines. But copy routines are the same! This is has to be an error of the Intel C++ optimizer, which still produces workable code, though.

We intentionally considering such example code in this book so the reader would understand that compiler output is weird at times, but still correct, because when the compiler was tested, it passed the tests.

### 3.9 Duff’s device

Duff’s device is an unrolled loop with the possibility to jump to the middle of it. The unrolled loop is implemented using a fallthrough switch() statement. We would use here a slightly simplified version of Tom Duff’s original code. Let’s say, we have to write a function that clears a region in memory. One can come with a simple loop, clearing byte by byte. It’s obviously slow, since all modern computers have much wider memory bus. So the better way is to clear the memory region using 4 or 8 bytes blocks. Since we are going to work with a 64-bit example here, we are going to clear the memory in 8 bytes blocks. So far so good. But what about the tail? Memory clearing routine can also be called for regions of size that’s not a multiple of 8. So here is the algorithm:

- calculate the number of 8-bytes blocks, clear them using 8-bytes (64-bit) memory accesses;
- calculate the size of the tail, clear it using 1-byte memory accesses.

The second step can be implemented using a simple loop. But let’s implement it as an unrolled loop:

```c
#include <stdint.h>
#include <stdio.h>

void bzero(uint8_t* dst, size_t count) {
  int i;
  if (count&(-7)) // work out 8-byte blocks
    for (i=0; i<count>>3; i++)
      {
```

[9]wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's first understand how the calculation is performed. The memory region size comes as a 64-bit value. And this value can be divided in two parts:

\[
\begin{array}{cccccccc}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\cdots & B & B & B & B & S & S & S \\
\end{array}
\]

(“B” is number of 8-byte blocks and “S” is length of the tail in bytes).

When we divide the input memory region size by 8, the value is just shifted right by 3 bits. But to calculate the remainder, we can just to isolate the lowest 3 bits! So the number of 8-byte blocks is calculated as \( \text{count} >> 3 \) and remainder as \( \text{count} \& 7 \). We also have to find out if we are going to execute the 8-byte procedure at all, so we need to check if the value of \( \text{count} \) is greater than 7. We do this by clearing the 3 lowest bits and comparing the resulting number with zero, because all we need here is to answer the question, is the high part of \( \text{count} \) non-zero. Of course, this works because 8 is \( 2^3 \) and division by numbers that are \( 2^n \) is easy. It’s not possible for other numbers. It’s actually hard to say if these hacks are worth using, because they lead to hard-to-read code. However, these tricks are very popular and a practicing programmer, even if he/she is not using them, nevertheless has to understand them.

So the first part is simple: get the number of 8-byte blocks and write 64-bit zero values to memory. The second part is an unrolled loop implemented as fallthrough switch() statement.

First, let’s express in plain English what we have to do here.

We have to “write as many zero bytes in memory, as \( \text{count} \& 7 \) value tells us”. If it’s 0, jump to the end, there is no work to do. If it’s 1, jump to the place inside switch() statement where only one storage operation is to be executed. If it’s 2, jump to another place, where two storage operation are to be executed, etc. 7 as input value leads to the execution of all 7 operations. There is no 8, because a memory region of 8 bytes is to be processed by the first part of our function. So we wrote an unrolled loop. It was definitely faster on older computers than normal loops (and conversely, latest CPUs works better for short loops than for unrolled ones). Maybe this is still meaningful on modern low-cost embedded MCU\(^\text{10}\)s.

Let’s see what the optimizing MSVC 2012 does:

```assembly
    dst$ = 8
    count$ = 16
    bzero PROC
        test     rdx, -8
        je       SHORT $LN11@bzero
        ; work out 8-byte blocks
        xor      r10d, r10d
        mov      r9, rdx
        shr      r9, 3
        mov      r8d, r10d
        test     r9, r9
        je       SHORT $LN11@bzero
        npad     5
$LL19@bzero:
        inc      r8d
        mov      QWORD PTR [rcx], r10
        add      rcx, 8
```

\(^\text{10}\)Microcontroller Unit

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
movsx rax, r8d
cmp rax, r9
jb SHORT $LL19@bzero

$LN11@bzero:
; work out the tail
and edx, 7
dec rdx
cmp rdx, 6
ja SHORT $LN9@bzero
lea r8, OFFSET FLAT:_ImageBase
mov eax, DWORD PTR $LN22@bzero[r8+rdx*4]
add rax, r8
jmp rax

$LN8@bzero:

DD $LN7@bzero
DD $LN8@bzero

bzero ENDP

The first part of the function is predictable. The second part is just an unrolled loop and a jump passing control flow to the correct instruction inside it. There is no other code between the MOV/INC instruction pairs, so the execution is to fall until the very end, executing as many pairs as needed. By the way, we can observe that the MOV/INC pair consumes a fixed number of bytes (3 + 3). So the pair consumes 6 bytes. Knowing that, we can get rid of the switch() jumptable, we can just multiple the input value by 6 and jump to \texttt{current RIP + input value * 6}.

This can also be faster because we are not in need to fetch a value from the jumptable.

It’s possible that 6 probably is not a very good constant for fast multiplication and maybe it’s not worth it, but you get the idea\textsuperscript{11}.

That is what old-school demomakers did in the past with unrolled loops.

### 3.9.1 Should one use unrolled loops?

Unrolled loops can have benefits if there is no fast cache memory between \texttt{RAM} and \texttt{CPU}, and the \texttt{CPU}, in order to get the code of the next instruction, must load it from \texttt{RAM} each time. This is a case of modern low-cost \texttt{MCU} and old \texttt{CPUs}.

\textsuperscript{11}As an exercise, you can try to rework the code to get rid of the jumptable. The instruction pair can be rewritten in a way that it will consume 4 bytes or maybe 8. 1 byte is also possible (using \texttt{STOSB} instruction).
Unrolled loops are slower than short loops if there is a fast cache between RAM and CPU and the body of loop can fit into cache, and CPU will load the code from it not touching the RAM. Fast loops are the loops which body’s size can fit into L1 cache, but even faster loops are those small ones which can fit into micro-operation cache.

### 3.10 Division using multiplication

A very simple function:

```c
int f(int a)
{
    return a/9;
}
```

#### 3.10.1 x86

...is compiled in a very predictable way:

Listing 3.19: MSVC

```assembly
.a$ = 8 ; size = 4
_f PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR_a$[ebp]
    cdq ; sign extend EAX to EDX:EAX
    mov ecx, 9
    idiv ecx
    pop ebp
    ret 0
_f ENDP
```

IDIV divides the 64-bit number stored in the EDX:EAX register pair by the value in the ECX. As a result, EAX will contain the quotient, and EDX— the remainder. The result is returned from the f() function in the EAX register, so the value is not moved after the division operation, it is in right place already.

Since IDIV uses the value in the EDX:EAX register pair, the CDQ instruction (before IDIV) extends the value in EAX to a 64-bit value taking its sign into account, just as MOVZX does.

If we turn optimization on (/Ox), we get:

Listing 3.20: Optimizing MSVC

```assembly
.a$ = 8 ; size = 4
_f PROC
    mov ecx, DWORD PTR_a$[esp-4]
    mov eax, 954437177 ; 38e38e39H
    imul ecx
    sar edx, 1
    mov eax, edx
    shr eax, 31 ; 00000001FH
    add eax, edx
    ret 0
_f ENDP
```

This is division by multiplication. Multiplication operations work much faster. And it is possible to use this trick to produce code which is effectively equivalent and faster.

This is also called “strength reduction” in compiler optimizations.

GCC 4.4.1 generates almost the same code even without additional optimization flags, just like MSVC with optimization turned on:

12Read more about division by multiplication in [Henry S. Warren, Hacker’s Delight, (2002)](http://example.com)

(For statistics collecting purposes) if you’ve read this far, please click [here](http://example.com). Thanks!
3.10.2 How it works

From school-level mathematics, we can remember that division by 9 can be replaced by multiplication by \( \frac{1}{9} \). In fact, sometimes compilers do so for floating-point arithmetics, for example, \texttt{FDIV} instruction in x86 code can be replaced by \texttt{FMUL}. At least MSVC 6.0 will replace division by 9 by multiplication by 0.111111... and sometimes it’s hard to be sure, what operation was in the original source code.

But when we operate over integer values and integer CPU registers, we can’t use fractions. However, we can rework fraction like that:

\[
\text{result} = \frac{x}{9} = x \cdot \frac{1}{9} = x \cdot \frac{1}{9 \cdot \text{MagicNumber}}
\]

Given the fact that division by \( 2^n \) is very fast (using shifts), we now should find that \textit{MagicNumber}, for which the following equation will be true: \( 2^n = 9 \cdot \text{MagicNumber} \).

Division by \( 2^{32} \) is somewhat hidden: lower 32-bit of product in EAX is not used (dropped), only higher 32-bit of product (in EDX) is used and then shifted by additional 1 bit.

In other words, the assembly code we have just seen multiplicates by \( \frac{954437177}{2^{32}+1} \), or divides by \( \frac{2^{32}+1}{954437177} \). To find a divisor we just have to divide numerator by denominator. Using Wolfram Alpha, we can get 8.99999999... as result (which is close to 9).

Many people miss “hidden” division by \( 2^{32} \) or \( 2^{64} \), when lower 32-bit part (or 64-bit part) of product is not used. This is why division by multiplication is difficult to understand at the beginning.

Mathematics for Programmers has yet another explanation.

3.10.3 ARM

The ARM processor, just like in any other “pure” RISC processor lacks an instruction for division. It also lacks a single instruction for multiplication by a 32-bit constant (recall that a 32-bit constant cannot fit into a 32-bit opcode).

By taking advantage of this clever trick (or \textit{hack}), it is possible to do division using only three instructions: addition, subtraction and bit shifts (1.28 on page 307).

Here is an example that divides a 32-bit number by 10, from [Advanced RISC Machines Ltd, \textit{The ARM Cookbook}, (1994)3.3 Division by a Constant]. The output consists of the quotient and the remainder.

\[\text{https://yurichev.com/writings/Math-for-programmers.pdf}\]
; takes argument in a1
; returns quotient in a1, remainder in a2
; cycles could be saved if only divide or remainder is required
SUB    a2, a1, #10      ; keep (x-10) for later
SUB    a1, a1, a1, lsr #2
ADD    a1, a1, a1, lsr #4
ADD    a1, a1, a1, lsr #8
ADD    a1, a1, a1, lsr #16
MOV    a1, a1, lsr #3
ADD    a3, a1, a1, asl #2
SUBS   a2, a2, a3, asl #1 ; calc (x-10) - (x/10)*10
ADDP   a1, a1, #1       ; fix-up quotient
ADDMI  a2, a2, #10      ; fix-up remainder
MOV    pc, lr

Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Memory Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV</td>
<td>R1, 0x38E38E39</td>
<td></td>
</tr>
<tr>
<td>SMMUL</td>
<td>R0, R0, R1</td>
<td></td>
</tr>
<tr>
<td>MOV</td>
<td>R1, R0, ASR#1</td>
<td></td>
</tr>
<tr>
<td>ADD</td>
<td>R0, R1, R0, LSR#31</td>
<td></td>
</tr>
<tr>
<td>BX</td>
<td>LR</td>
<td></td>
</tr>
</tbody>
</table>

This code is almost the same as the one generated by the optimizing MSVC and GCC.

Apparently, LLVM uses the same algorithm for generating constants.

The observant reader may ask, how does MOV writes a 32-bit value in a register, when this is not possible in ARM mode.

It is impossible indeed, but, as we see, there are 8 bytes per instruction instead of the standard 4, in fact, there are two instructions.

The first instruction loads 0x8E39 into the low 16 bits of register and the second instruction is MOV, it loads 0x383E into the high 16 bits of the register. IDA is fully aware of such sequences, and for the sake of compactness reduces them to one single “pseudo-instruction”.

The SMMUL (Signed Most Significant Word Multiply) instruction two multiplies numbers, treating them as signed numbers and leaving the high 32-bit part of result in the R0 register, dropping the low 32-bit part of the result.

The “MOV R1, R0, ASR#1” instruction is an arithmetic shift right by one bit.

“ADD R0, R1, R0, LSR#31” is \(R0 = R1 + R0 >> 31\)

There is no separate shifting instruction in ARM mode. Instead, an instructions like (MOV, ADD, SUB, RSB) can have a suffix added, that says if the second operand must be shifted, and if yes, by what value and how. ASR stands for Arithmetic Shift Right, LSR—Logical Shift Right.

Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Memory Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV</td>
<td>R1, 0x38E38E39</td>
<td></td>
</tr>
<tr>
<td>SMMUL.W</td>
<td>R0, R0, R1</td>
<td></td>
</tr>
<tr>
<td>ASRS</td>
<td>R1, R0, #1</td>
<td></td>
</tr>
<tr>
<td>ADD.W</td>
<td>R0, R1, R0, LSR#31</td>
<td></td>
</tr>
<tr>
<td>BX</td>
<td>LR</td>
<td></td>
</tr>
</tbody>
</table>

There are separate instructions for shifting in Thumb mode, and one of them is used here—ASRS (arithmetic shift right).

\(^{14}\)These instructions are also called “data processing instructions”
Non-optimizing Xcode 4.6.3 (LLVM) and Keil 6/2013

Non-optimizing LLVM does not generate the code we saw before in this section, but instead inserts a call to the library function __divsi3.

What about Keil: it inserts a call to the library function __aeabi_idivmod in all cases.

### 3.10.4 MIPS

For some reason, optimizing GCC 4.4.5 generate just a division instruction:

<table>
<thead>
<tr>
<th>Listing 3.22: Optimizing GCC 4.4.5 (IDA)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>f:</code></td>
</tr>
<tr>
<td>li $v0, 9</td>
</tr>
<tr>
<td>bnez $v0, loc_10</td>
</tr>
<tr>
<td>div $a0, $v0; branch delay slot</td>
</tr>
<tr>
<td>break 0x1C00</td>
</tr>
<tr>
<td>loc_10:</td>
</tr>
<tr>
<td>mflo $v0</td>
</tr>
<tr>
<td>jr $ra</td>
</tr>
<tr>
<td>or $at, $zero; branch delay slot, NOP</td>
</tr>
</tbody>
</table>

Here we see here a new instruction: BREAK. It just raises an exception.

In this case, an exception is raised if the divisor is zero (it’s not possible to divide by zero in conventional math).

But GCC probably did not do very well the optimization job and did not see that $V0 is never zero.

So the check is left here. So if $V0 is zero somehow, BREAK is to be executed, signaling to the OS about the exception.

Otherwise, MFLO executes, which takes the result of the division from the LO register and copies it in $V0.

By the way, as we may know, the MUL instruction leaves the high 32 bits of the result in register HI and the low 32 bits in register LO.

DIV leaves the result in the LO register, and remainder in the HI register.

If we alter the statement to “a % 9”, the MFHI instruction is to be used here instead of MFLO.

### 3.10.5 Exercise

- [http://challenges.re/27](http://challenges.re/27)

### 3.11 String to number conversion (atoi())

Let's try to reimplement the standard atoi() C function.

#### 3.11.1 Simple example

Here is the simplest possible way to read a number represented in ASCII encoding.

It's not error-prone: a character other than a digit leads to incorrect result.

```c
#include <stdio.h>

int my_atoi (char *s)
{
    int rt=0;
    while (*s)
    {
```

(For statistics collecting purposes) if you've read this far, please click [here](http://challenges.re/27). Thanks!
So what the algorithm does is just reading digits from left to right.
The zero ASCII character is subtracted from each digit.
The digits from “0” to “9” are consecutive in the ASCII table, so we do not even need to know the exact value of the “0” character.
All we have to know is that “0” minus “0” is 0, “9” minus “0” is 9 and so on.
Subtracting “0” from each character results in a number from 0 to 9 inclusive.
Any other character leads to an incorrect result, of course!
Each digit has to be added to the final result (in variable “rt”), but the final result is also multiplied by 10 at each digit.
In other words, the result is shifted left by one position in decimal form on each iteration.
The last digit is added, but there is no shift.

Optimizing MSVC 2013 x64

A character can be loaded in two places: the first character and all subsequent characters. This is arranged so for loop regrouping.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There is no instruction for multiplication by 10, two LEA instruction do this instead.

MSVC sometimes uses the ADD instruction with a negative constant instead of SUB. This is the case.
It’s very hard to say why this is better then SUB. But MSVC does this often.

**Optimizing GCC 4.9.1 x64**

Optimizing GCC 4.9.1 is more concise, but there is one redundant RET instruction at the end. One would be enough.

```
Listing 3.24: Optimizing GCC 4.9.1 x64

my_atoi:
    ; load input character into EDX
    movsx    edx, BYTE PTR [rdi]
    ; EAX is allocated for "rt" variable
    xor      eax, eax
    ; exit, if loaded character is null byte
    test     dl, dl
    je      .L4
    .L3:
        lea     eax, [rax+rax*4]
        ; EAX=RAX*5=rt*5
        add     rdi, 1
        lea     eax, [rdx-48+rax*2]
        ; EAX=input character - 48 + RAX*2 = input character - '0' + rt*10
        movsx    edx, BYTE PTR [rdi]
        ; goto loop begin, if loaded character is not null byte
        test     dl, dl
        jne     .L3
    rep ret
    .L4:
        rep ret
```

**Optimizing Keil 6/2013 (ARM mode)**

```
Listing 3.25: Optimizing Keil 6/2013 (ARM mode)

my_atoi PROC
    ; R1 will contain pointer to character
    MOV     r1,r0
    ; R0 will contain "rt" variable
    MOV     r0,#0
    B      |L0.12|
    |L0.12|
    ADD      r0,r0,r0,LSL #2
    ; R0=R0+R0<<2=rt*5
    ADD      r0,r2,r0,LSL #1
    ; R0=input character + rt*5<<1 = input character + rt*10
    ; correct whole thing by subtracting '0' from rt:
    SUB      r0,r0,#0x30
    ; shift pointer to the next character:
    ADD      r1,r1,1
    |L0.28|
    ; load input character to R2
    LDRB     r2,[r1,#0]
    ; is it null byte? if no, jump to loop body.
    CMP      r2,#0
    BNE    |L0.12|
    ; exit if null byte.
    ; "rt" variable is still in R0 register, ready to be used in caller function
    BX      lr
ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Optimizing Keil 6/2013 (Thumb mode)

Listing 3.26: Optimizing Keil 6/2013 (Thumb mode)

```assembly
my_atoi PROC
  ; R1 will be pointer to the input character
  MOV r1, r0
  ; R0 is allocated to "rt" variable
  MOV r0, #0
  B |L0.6|

  |L0.6|
  MOV r3, #0xa
  ; R3=10
  MULS r0, r3, r0
  ; R0=R3*R0=rt*10
  ADDS r1, r1, #1
  ; shift pointer to the next character:
  SUBS r0, r0, #0x30
  ADDS r0, r2, r0
  ; rt=R2+R0=input character + (rt*10 - '0')

  |L0.16|
  ; load input character to R2
  LDRB r2, [r1, #0]
  ; is it zero?
  CMP r2, #0
  BNE |L0.6|

  ; rt variable in R0 now, ready to be used in caller function
  BX lr
ENDP
```

Interestingly, from school mathematics we may recall that the order of addition and subtraction operations doesn’t matter.

That’s our case: first, the \( rt \times 10 - '0' \) expression is computed, then the input character value is added to it. Indeed, the result is the same, but the compiler did some regrouping.

Optimizing GCC 4.9.1 ARM64

The ARM64 compiler can use the pre-increment instruction suffix:

Listing 3.27: Optimizing GCC 4.9.1 ARM64

```assembly
my_atoi:
  ; load input character into W1
  ldrb w1, [x0]
    mov x2, x0
  ; X2=address of input string
  ; is loaded character zero?
  ; jump to exit if its so
  ; W1 will contain 0 in this case.
  ; it will be reloaded into W0 at L4.
    cbz w1, .L4

  ; W0 will contain "rt" variable
  ; initialize it at zero:
    mov w0, 0

  .L3:
  ; subtract 48 or '0' from input variable and put result into W3:
    sub w3, w1, #48
  ; load next character at address X2+1 into W1 with pre-increment:
    ldrb w1, [x2,1]!
    add w0, w0, w0, lsl 2
    W0=W0+W0<<2=W0+W0*4=rt*5
    add w0, w3, w0, lsl 1
    W0=input digit + W0<<1 = input digit + rt*5*2 = input digit + rt*10
  ; if the character we just loaded is not null byte, jump to the loop begin
    cbnz w1, .L3
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.11.2 A slightly advanced example

My new code snippet is more advanced, now it checks for the “minus” sign at the first character and reports an error if a non-digit has been found in the input string:

```c
#include <stdio.h>

int my_atoi (char *s)
{
    int negative=0;
    int rt=0;
    if (*s=='-')
    {
        negative=1;
        s++;
    }
    while (*s)
    {
        if (*s<0 || *s>'9')
        {
            printf ("Error! Unexpected char: '\%c'\n", *s);
            exit(0);
        }
        rt=rt*10 + (*s-'0');
        s++;
    }
    if (negative)
        return -rt;
    return rt;
}

int main()
{
    printf ("%d\n", my_atoi ("1234"));
    printf ("%d\n", my_atoi ("1234567890"));
    printf ("%d\n", my_atoi ("-1234"));
    printf ("%d\n", my_atoi ("-1234567890"));
    printf ("%d\n", my_atoi ("-a1234567890")); // error
}
```

Optimizing GCC 4.9.1 x64

```asm
.LC0:
    .string "Error! Unexpected char: '\%c'\n"

my_atoi:
    sub    rsp, 8
    movsx  edx, BYTE PTR [rdi]
; check for minus sign
    cmp     dl, 45 ; '\-
    je      .L22
    xor     esi, esi
    test    dl, dl
    je      .L20
.L10:
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
ESI=0 here if there was no minus sign and 1 if it was

lea    eax, [rdx-48]
; any character other than digit will result in unsigned number greater than 9 after subtraction
; so if it is not digit, jump to L4, where error will be reported:
       cmp    al, 9
       ja     .L4
       xor    eax, eax
       jmp    .L6

.L7:
       lea    ecx, [rdx-48]
       cmp    cl, 9
       ja     .L4

.L6:
       lea    eax, [rax+rax*4]
       add    rdi, 1
       lea    eax, [rdx-48+rax*2]
       movsx  edx, BYTE PTR [rdi]
       test   dl, dl
       jne    .L7

; if there was no minus sign, skip NEG instruction
; if it was, execute it.
       test    esi, esi
       je      .L18
       neg    eax

.L18:
       add    rsp, 8
       ret

.L22:
       movsx  edx, BYTE PTR [rdi+1]
       lea    rax, [rdi+1]
       test   dl, dl
       je      .L20
       mov    rdi, rax
       mov    esi, 1
       jmp    .L10

.L20:
       xor    eax, eax
       jmp    .L18

.L4:
; report error. character is in EDX
       mov    edi, 1
       mov    esi, OFFSET FLAT:.LC0
       "Error! Unexpected char: '%c'\n"
       xor    eax, eax
       call   __printf_chk
       xor    edi, edi
       call   exit

If the “minus” sign has been encountered at the string start, the NEG instruction is to be executed at the end. It just negates the number.

There is one more thing that needs mentioning.

How would a common programmer check if the character is not a digit? Just how we have it in the source code:

```c
if (*s<'0' || *s>'9')
```

There are two comparison operations.

What is interesting is that we can replace both operations by single one: just subtract “0” from character value,
treat result as unsigned value (this is important) and check if it’s greater than 9.

For example, let’s say that the user input contains the dot character (“.”) which has ASCII code 46.
46 - 48 = -2 if we treat the result as a signed number.

Indeed, the dot character is located two places earlier than the “0” character in the ASCII table. But it is 0xFFFFFFF0 (4294967294) if we treat the result as an unsigned value, and that’s definitely bigger than 9!
The compilers do this often, so it’s important to recognize these tricks.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Another example of it in this book: \textbf{3.17.1 on page 542.}

Optimizing MSVC 2013 x64 does the same tricks.

**Optimizing Keil 6/2013 (ARM mode)**

Listing 3.29: Optimizing Keil 6/2013 (ARM mode)

```assembly
my_atoi PROC
  PUSH {r4-r6,lr}
  MOV r4,r0
  LDRB r0,[r0,#0]
  MOV r6,#0
  MOV r5,r6
  CMP r0,#0x2d '

; R6 will contain 1 if minus was encountered, 0 if otherwise
  MOVEQ r6,#1
  ADDEQ r4,r4,#1
  B |L0.80|

|L0.36|
  SUB r0,r1,#0x30
  CMP r0,#0xa
  BCC |L0.64|
  ADR r0,|L0.220|
  BL __2printf
  MOV r0,#0
  BL exit

|L0.64|
  LDRB r0,[r4],#1
  ADD r1,r5,r5,LSL #2
  ADD r0,r0,r1,LSL #1
  SUB r5,r0,#0x30

|L0.80|
  LDRB r1,[r4,#0]
  CMP r1,#0
  BNE |L0.36|
  CMP r6,#0

; negate result
  RSBNE r0,r5,#0
  MOVEQ r0,r5
  POP {r4-r6,pc}
  ENDP

|L0.220|
  DCB "Error! Unexpected char: '%c'\n",0
```

There is no NEG instruction in 32-bit ARM, so the “Reverse Subtraction” operation (line 31) is used here. It is triggered if the result of the CMP instruction (at line 29) has been “Not Equal” (hence -NE suffix). So what RSBNE does is to subtract the resulting value from 0.

It works just like the regular subtraction operation, but swaps operands.

Subtracting any number from 0 results in negation: \(0 - x = -x\).

Thumb mode code is mostly the same.

GCC 4.9 for ARM64 can use the NEG instruction, which is available in ARM64.

### 3.11.3 Exercise

Oh, by the way, security researchers deals often with unpredictable behavior of program while handling of incorrect data.

For example, while fuzzing. As an exercise, you may try to enter non-digit characters and see what happens.

Try to explain, what happened and why.
3.12 Inline functions

Inlined code is when the compiler, instead of placing a call instruction to a small or tiny function, just places its body right in-place.

Listing 3.30: A simple example

```c
#include <stdio.h>

int celsius_to_fahrenheit (int celsius)
{
    return celsius * 9 / 5 + 32;
};

int main(int argc, char *argv[])
{
    int celsius = atol(argv[1]);
    printf (“%d\n”, celsius_to_fahrenheit (celsius));
};
```

...is compiled in very predictable way, however, if we turn on GCC optimizations (-O3), we’ll see:

Listing 3.31: Optimizing GCC 4.8.1

```
_main:
push   ebp
mov    ebp, esp
and    esp, -16
sub    esp, 16
call   ___main
mov    eax, DWORD PTR [ebp+12]
mov    eax, DWORD PTR [eax+4]
mov    DWORD PTR [esp], eax
call   _atol
mov    edx, 1717986919
mov    DWORD PTR [esp], OFFSET FLAT:LC2 ; “%d\n”
lea    ecx, [eax+eax*8]
mov    eax, ecx
imul   edx
sar    ecx, 31
sar    edx
sub    edx, ecx
add    edx, 32
mov    DWORD PTR [esp+4], edx
call   _printf
leave
ret
```

(Here the division is performed by multiplication(3.10 on page 504).)

Yes, our small function celsius_to_fahrenheit() has just been placed before the printf() call.

Why? It can be faster than executing this function’s code plus the overhead of calling/returning.

Modern optimizing compilers are choosing small functions for inlining automatically. But it’s possible to force compiler additionally to inline some function, if to mark it with the “inline” keyword in its declaration.

3.12.1 Strings and memory functions

Another very common automatic optimization tactic is the inlining of string functions like strcpy(), strcmp(), strlen(), memset(), memcmp(), memcpy(), etc..

Sometimes it’s faster than to call a separate function.

These are very frequent patterns and it is highly advisable for reverse engineers to learn to detect automatically.
Listing 3.32: strcmp() example

```c
bool is_bool (char *s)
{
    if (strcmp (s, "true")==0)
        return true;
    if (strcmp (s, "false")==0)
        return false;
    assert(0);
}
```

Listing 3.33: Optimizing GCC 4.8.1

```
.LC0: .string "true"
.LC1: .string "false"
is_bool:
.LFB0:
push   edi
    mov   ecx, 5
    push   esi
    mov   edi, OFFSET FLAT:.LC0
    sub   esp, 20
    mov   esi, DWORD PTR [esp+32]
    repz cmpsb
    je   .L3
    mov   esi, DWORD PTR [esp+32]
    mov   ecx, 6
    mov   edi, OFFSET FLAT:.LC1
    repz cmpsb
    seta  cl
    setb  dl
    xor   eax, eax
    cmp   cl, dl
    jne   .L8
    add   esp, 20
    pop   esi
    pop   edi
    ret
.L8:
    mov   DWORD PTR [esp], 0
    call  assert
    add   esp, 20
    pop   esi
    pop   edi
    ret
.L3:
    add   esp, 20
    mov   eax, 1
    pop   esi
    pop   edi
    ret
```

Listing 3.34: Optimizing MSVC 2010

```

### strlen()

Listing 3.35: strlen() example

```c
int strlen_test(char *s1)
{
    return strlen(s1);
}
```

### Optimizing MSVC 2010

Listing 3.36: Optimizing MSVC 2010

```assembly
_sl1$ = 8 ; size = 4
_strlen_test PROC
    mov  eax, DWORD PTR _sl1$[esp-4]
    lea  edx, DWORD PTR [eax+1]
$L3@strlen_tes:
    mov  cl, BYTE PTR [eax]
    inc  eax
    test cl, cl
    jne  SHORT $L3@strlen_tes
    sub  eax, edx
    ret 0
_strlen_test ENDP
```

### strcpy()

Listing 3.37: strcpy() example

```c
void strcpy_test(char *s1, char *outbuf)
{
    strcpy(outbuf, s1);
}
```

### Optimizing MSVC 2010

Listing 3.38: Optimizing MSVC 2010

```assembly
_sl1$ = 8 ; size = 4
_outbuf$ = 12 ; size = 4
strcpy_test PROC
    mov  eax, DWORD PTR _sl1$[esp-4]
    mov  edx, DWORD PTR _outbuf$[esp-4]
    sub  edx, eax
    npad 6 ; align next label
$L3@strcpy_tes:
    mov  cl, BYTE PTR [eax]
    mov  BYTE PTR [edx+eax], cl
    inc  eax
    test cl, cl
    jne  SHORT $L3@strcpy_tes
    ret 0
strcpy_test ENDP
```

### memset()

#### Example#1

Listing 3.39: 32 bytes

```c
#include <stdio.h>

void f(char *out)
{
    memset(out, 0, 32);
}
```

Many compilers don't generate a call to memset() for short blocks, but rather insert a pack of MOVs:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Listing 3.40: Optimizing GCC 4.9.1 x64

```c
f:
    mov QWORD PTR [rdi], 0
    mov QWORD PTR [rdi+8], 0
    mov QWORD PTR [rdi+16], 0
    mov QWORD PTR [rdi+24], 0
    ret
```

By the way, that remind us of unrolled loops: [1.22.1 on page 194](#).

**Example#2**

Listing 3.41: 67 bytes

```c
#include <stdio.h>

void f(char *out)
{
    memset(out, 0, 67);
}
```

When the block size is not a multiple of 4 or 8, the compilers can behave differently. For instance, MSVC 2012 continues to insert MOVs:

Listing 3.42: Optimizing MSVC 2012 x64

```c
out$ = 8
f PROC
    xor eax, eax
    mov QWORD PTR [rcx], rax
    mov QWORD PTR [rcx+8], rax
    mov QWORD PTR [rcx+16], rax
    mov QWORD PTR [rcx+24], rax
    mov QWORD PTR [rcx+32], rax
    mov QWORD PTR [rcx+40], rax
    mov QWORD PTR [rcx+48], rax
    mov QWORD PTR [rcx+56], rax
    mov WORD PTR [rcx+64], ax
    mov BYTE PTR [rcx+66], al
    ret 0
f ENDP
```

...while GCC uses REP STOSQ, concluding that this would be shorter than a pack of MOVs:

Listing 3.43: Optimizing GCC 4.9.1 x64

```c
f:
    mov QWORD PTR [rdi], 0
    mov QWORD PTR [rdi+59], 0
    mov rcx, rdi
    lea rdi, [rdi+8]
    xor eax, eax
    and rdi, -8
    sub rcx, rdi
    add ecx, 67
    shr ecx, 3
    rep stosq
    ret
```

**memcpy()**

**Short blocks**

The routine to copy short blocks is often implemented as a sequence of MOV instructions.

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Listing 3.44: memcpy() example
void memcpy_7(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 7);
};

Listing 3.45: Optimizing MSVC 2010
_inbuf$ = 8      ; size = 4
_outbuf$ = 12    ; size = 4
memcpy_7 PROC
    mov    ecx, DWORD PTR _inbuf$[esp-4]
    mov    edx, DWORD PTR [ecx]
    mov    eax, DWORD PTR _outbuf$[esp-4]
    mov    edx, DWORD PTR [eax+10], edx
    mov    dx, WORD PTR [ecx+4]
    mov    dx, WORD PTR [eax+14], dx
    mov    cl, BYTE PTR [ecx+6]
    mov    dx, BYTE PTR [eax+16], cl
ret 0
memcpy_7 ENDP

Listing 3.46: Optimizing GCC 4.8.1
memcpy_7:
    push   ebx
    mov    eax, DWORD PTR [esp+8]
    mov    ecx, DWORD PTR [esp+12]
    mov    ebx, DWORD PTR [eax]
    lea    edx, [ecx+10]
    mov    edx, DWORD PTR [ecx+10], ebx
    movzx   ecx, WORD PTR [eax+4]
    mov    edx, WORD PTR [edx+4], cx
movzx   ecx, BYTE PTR [eax+6]
    mov    edx, BYTE PTR [edx+6], al
pop     ebx
ret

That’s usually done as follows: 4-byte blocks are copied first, then a 16-bit word (if needed), then the last byte (if needed).

Structures are also copied using MOV: 1.30.4 on page 365.

Long blocks

The compilers behave differently in this case.

Listing 3.47: memcpy() example
void memcpy_128(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 128);
};
void memcpy_123(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 123);
};

For copying 128 bytes, MSVC uses a single MOVSD instruction (because 128 divides evenly by 4):

Listing 3.48: Optimizing MSVC 2010
_inbuf$ = 8      ; size = 4
_outbuf$ = 12    ; size = 4
memcpy_128 PROC
    push   esi
    mov    esi, DWORD PTR _inbuf$[esp]
    mov    ecx, DWORD PTR _inbuf$[esp+10]
    mov    edx, DWORD PTR [ecx+4]
    mov    cl, BYTE PTR [ecx+6]
ret 0
memcpy_128 ENDP

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
When copying 123 bytes, 30 32-bit words are copied first using MOVSD (that’s 120 bytes), then 2 bytes are copied using MOVSW, then one more byte using MOVSB.

Listing 3.49: Optimizing MSVC 2010

```
inbuf$ = 8 ; size = 4
_outbuf$ = 12 ; size = 4
_memcpy_123 PROC
    push esi
    mov esi, DWORD PTR _inbuf$[esp]
    push edi
    mov edi, DWORD PTR _outbuf$[esp+4]
    add edi, 10
    mov ecx, 30
    rep movsd
    movsw
    movsb
    pop edi
    pop esi
    ret 0
_memcpy_123 ENDP
```

GCC uses one big universal functions, that works for any block size:

Listing 3.50: Optimizing GCC 4.8.1

```
memcpy_123:
.LFB3:
    push edi
    mov eax, 123
    push esi
    mov edx, DWORD PTR [esp+16]
    mov esi, DWORD PTR [esp+12]
    lea edi, [edx+10]
    test edi, 1
    jne .L24
    test edi, 2
    jne .L25
    .L7:
        mov ecx, eax
        xor edx, edx
        shr ecx, 2
        test al, 2
        rep movsd
        je .L8
        movzx edx, WORD PTR [esi]
        mov WORD PTR [edi], dx
        mov edx, 2
        .L8:
            test al, 1
            je .L5
            movzx eax, BYTE PTR [esi+edx]
            mov BYTE PTR [edi+edx], al
            .L5:
                pop esi
                pop edi
                ret
            .L24:
                movzx eax, BYTE PTR [esi]
                lea edi, [edx+11]
                add esi, 1
```
Universal memory copy functions usually work as follows: calculate how many 32-bit words can be copied, then copy them using MOVSD, then copy the remaining bytes.

More advanced and complex copy functions use SIMD instructions and also take the memory alignment in consideration.

As an example of SIMD strlen() function: 1.36.2 on page 421.

memcmp()

Listing 3.51: memcmp() example

```c
int memcmp_1235(char *buf1, char *buf2)
{
    return memcmp(buf1, buf2, 1235);
}
```

For any block size, MSVC 2013 inserts the same universal function:

Listing 3.52: Optimizing MSVC 2010

```assembly
buf1$ = 8 ; size = 4
buf2$ = 12 ; size = 4
_memcmp_1235 PROC
    mov    ecx, DWORD PTR _buf1$[esp-4]
    mov    edx, DWORD PTR _buf2$[esp-4]
    push   esi
    mov    esi, 1231
    npad   2 $LL5@memcmp_123:
        mov    eax, DWORD PTR _buf1$[ecx]
        cmp    eax, DWORD PTR _buf2$[edx]
        jne    SHORT $LN4@memcmp_123
        add    ecx, 4
        add    edx, 4
        sub    esi, 4
        jae    SHORT $LL5@memcmp_123 $LN4@memcmp_123:
            mov    al, BYTE PTR [ecx]
            cmp    al, BYTE PTR [edx]
            jne    SHORT $LN6@memcmp_123
            cmp    al, BYTE PTR [ecx+1]
            jne    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [ecx+1]
            jmp    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [ecx+2]
            jmp    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [ecx+2]
            jmp    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [edx+2]
            jmp    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [edx+2]
            jmp    SHORT $LN6@memcmp_123
            cmp    esi, -1
            je      SHORT $LN3@memcmp_123
            mov    al, BYTE PTR [ecx+3]
            cmp    al, BYTE PTR [edx+3]
            jne    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [ecx+3]
            jmp    SHORT $LN6@memcmp_123
            mov    al, BYTE PTR [edx+3]
            jmp    SHORT $LN6@memcmp_123
            xor    eax, eax
            pop    esi
            ret 0

$LN3@memcmp_123:
```
$LN6@memcmp_123:
    sbb    eax, eax
    or     eax, 1
    pop    esi
    ret    0
 memcmp_1235 ENDP

strcat()

This is inlined strcat() as it has been generated by MSVC 6.0. There are 3 parts visible: 1) getting source string length (first scasb); 2) getting destination string length (second scasb); 3) copying source string into the end of destination string (movsd/movsb pair).

Listing 3.53: strcat()

<table>

IDA script

There is also a small IDA script for searching and folding such very frequently seen pieces of inline code: GitHub.

3.13 C99 restrict

Here is a reason why Fortran programs, in some cases, work faster than C/C++ ones.

```c
void f1 (int* x, int* y, int* sum, int* product, int* sum_product, int* update_me, size_t s) {
    for (int i=0; i<s; i++)
    {
        sum[i]=x[i]+y[i];
        product[i]=x[i]*y[i];
        update_me[i]=i*123;  // some dummy value
        sum_product[i]=sum[i]+product[i];
    }
};
```

That’s very simple example with one specific thing in it: the pointer to the update_me array could be a pointer to the sum array, product array, or even the sum_product array—nothing forbids that, right?
The compiler is fully aware of this, so it generates code with four stages in the loop body:

- calculate next sum[i]
- calculate next product[i]
- calculate next update_me[i]
• calculate next sum_product[i]—on this stage, we need to load from memory the already calculated sum[i] and product[i]

Is it possible to optimize the last stage? Since we have already calculated sum[i] and product[i] it is not necessary to load them again from memory.

Yes, but compiler is not sure that nothing has been overwritten at the 3rd stage! This is called “pointer aliasing”, a situation when the compiler cannot be sure that a memory to which a pointer is pointing hasn’t been changed.

restrict in the C99 standard [ISO/IEC 9899:TC3 (C99 standard), (2007) 6.7.3/1] is a promise, given by programmer to the compiler that the function arguments marked by this keyword always points to different memory locations and never intersects.

To be more precise and describe this formally, restrict shows that only this pointer is to be used to access an object, and no other pointer will be used for it.

It can be even said the object will be accessed only via one single pointer, if it is marked as restrict.

Let’s add this keyword to each pointer argument:

```c
void f2 (int* restrict x, int* restrict y, int* restrict sum, int* restrict product, int* restrict sum_product, size_t s)
{
    for (int i=0; i<s; i++)
    {
        sum[i]=x[i]+y[i];
        product[i]=x[i]*y[i];
        update_me[i]=i*123; // some dummy value
        sum_product[i]=sum[i]+product[i];
    }
}
```

Let’s see results:

Listing 3.54: GCC x64: f1()
The difference between the compiled f1() and f2() functions is as follows: in f1(), sum[i] and product[i] are reloaded in the middle of the loop, and in f2() there is no such thing, the already calculated values are used, since we “promised” the compiler that no one and nothing will change the values in sum[i] and product[i] during the execution of the loop’s body, so it is “sure” that there is no need to load the value from memory again.

Obviously, the second example works faster.

But what if the pointers in the function’s arguments intersect somehow? This is on the programmer’s conscience, and the results will be incorrect.

Let’s go back to Fortran.

Compilers of this programming language treats all pointers as such, so when it was not possible to set restrict in C, Fortran could generate faster code in these cases.

How practical is it?

In the cases when the function works with several big blocks in memory.

There are a lot of such in linear algebra, for instance.

Supercomputers/HPC are very busy with linear algebra, so probably that is why, traditionally, Fortran is still used there [Eugene Loh, The Ideal HPC Programming Language, (2010)].

But when the number of iterations is not very big, certainly, the speed boost may not to be significant.

\[\text{High-Performance Computing}\]
3.14 Branchless abs() function

Let’s revisit an example we considered earlier 1.18.2 on page 141 and ask ourselves, is it possible to make a branchless version of the function in x86 code?

```c
int my_abs (int i)
{
    if (i<0)
        return -i;
    else
        return i;
}
```

And the answer is yes.

3.14.1 Optimizing GCC 4.9.1 x64

We could see it if we compile it using optimizing GCC 4.9:

```plaintext
Listing 3.56: Optimizing GCC 4.9 x64

my_abs:
  mov  edx, edi
  mov  eax, edi
  sar  edx, 31
  ; EDX is 0xFFFFFFFF here if sign of input value is minus
  ; EDX is 0 if sign of input value is plus (including 0)
  ; the following two instructions have effect only if EDX is 0xFFFFFFFF
  ; or idle if EDX is 0
  xor  eax, edx
  sub  eax, edx
  ret
```

This is how it works:

Arithmetically shift the input value right by 31.

Arithmetical shift implies sign extension, so if the MSB is 1, all 32 bits are to be filled with 1, or with 0 if otherwise.

In other words, the SAR REG, 31 instruction makes 0xFFFFFFFF if the sign has been negative or 0 if positive.

After the execution of SAR, we have this value in EDX.

Then, if the value is 0xFFFFFFFF (i.e., the sign is negative), the input value is inverted (because XOR REG, 0xFFFFFFFF is effectively an inverse all bits operation).

Then, again, if the value is 0xFFFFFFFF (i.e., the sign is negative), 1 is added to the final result (because subtracting −1 from some value resulting in incrementing it).

Inversion of all bits and incrementing is exactly how two’s complement value is negated: 2.2 on page 458.

We may observe that the last two instruction do something if the sign of the input value is negative. Otherwise (if the sign is positive) they do nothing at all, leaving the input value untouched.

The algorithm is explained in [Henry S. Warren, Hacker’s Delight, (2002)2-4].

It’s hard to say, how GCC did it, deduced it by itself or found a suitable pattern among known ones?

3.14.2 Optimizing GCC 4.9 ARM64

GCC 4.9 for ARM64 generates mostly the same, just decides to use the full 64-bit registers.

There are less instructions, because the input value can be shifted using a suffixed instruction (“asr”) instead of using a separate instruction.
3.15 Variadic functions

Functions like `printf()` and `scanf()` can have a variable number of arguments. How are these arguments accessed?

3.15.1 Computing arithmetic mean

Let's imagine that we want to calculate arithmetic mean, and for some weird reason we want to specify all the values as function arguments.

But it's impossible to get the number of arguments in a variadic function in C/C++, so let's denote the value of −1 as a terminator.

Using va_arg macro

There is the standard stdarg.h header file which define macros for dealing with such arguments. The `printf()` and `scanf()` functions use them as well.

```c
#include <stdio.h>
#include <stdarg.h>

int arith_mean(int v, ...) {
    va_list args;
    int sum=v, count=1, i;
    va_start(args, v);

    while(1)
    {
        i=va_arg(args, int);
        if (i==-1) // terminator
            break;
        sum=sum+i;
        count++;
    }
    va_end(args);
    return sum/count;
};

int main() {
    printf ("%d\n", arith_mean (1, 2, 7, 10, 15, -1 /* terminator */));
};
```

The first argument has to be treated just like a normal argument.

All other arguments are loaded using the va_arg macro and then summed.

So what is inside?
The arguments, as we may see, are passed to main() one-by-one.
The first argument is pushed into the local stack as first.
The terminating value (−1) is pushed last.
The arith_mean() function takes the value of the first argument and stores it in the sum variable.
Then, it sets the EDX register to the address of the second argument, takes the value from it, adds it to sum, and does this in an infinite loop, until −1 is found.
When it’s found, the sum is divided by the number of all values (excluding −1) and the quotient is returned.
So, in other words, the function treats the stack fragment as an array of integer values of infinite length.
Now we can understand why the cdecl calling convention forces us to push the first argument into the stack as last.
Because otherwise, it would not be possible to find the first argument, or, for printf-like functions, it would not be possible to find the address of the format-string.

Register-based calling conventions

The observant reader may ask, what about calling conventions where the first few arguments are passed in registers? Let’s see:
Listing 3.59: Optimizing MSVC 2012 x64

$v$ = 8

```
$SG3013 DB 'd', 0aH, 00H

; 1st argument
mov DWORD PTR [rsp+8], ecx

; 2nd argument
mov QWORD PTR [rsp+16], rdx

; 3rd argument
mov QWORD PTR [rsp+24], r8

; sum = 1st argument
mov eax, ecx

; pointer to the 2nd argument
lea rcx, QWORD PTR v$[rsp+8]

; load 2nd argument
mov edx, DWORD PTR [rcx]

; count=1
mov r8d, 1

; 2nd argument is -1?
cmp edx, -1
je SHORT $LL3@arith_mean

; sum = sum + loaded argument
add eax, edx

; load next argument
mov edx, DWORD PTR [rcx+8]

; shift pointer to point to the argument after next
inc r8d

; is loaded argument -1?
jne SHORT $LL3@arith_mean

; calculate quotient
cdq
idiv r8d
ret 0
```

Main Proc

```
main PROC

sub rbp, 56
mov edx, 2
mov DWORD PTR [ebp+40], -1
mov DWORD PTR [ebp+32], 15
lea r9d, QWORD PTR [rdx+8]
lea r8d, QWORD PTR [rdx+5]
lea ecx, QWORD PTR [rdx-1]
call arith_mean
lea rcx, OFFSET FLAT:$SG3013
mov edx, eax
call printf
xor eax, eax
add rbp, 56
ret 0
main ENDP
```

We see that the first 4 arguments are passed in the registers and two more—in the stack.

The arith_mean() function first places these 4 arguments into the Shadow Space and then treats the Shadow Space and stack behind it as a single continuous array!

What about GCC? Things are slightly clumsier here, because now the function is divided in two parts: the first part saves the registers into the “red zone”, processes that space, and the second part of the function processes the stack:

Listing 3.60: Optimizing GCC 4.9.1 x64

```
arith_mean:
    lea rax, [rsp+8]
    ; save 6 input registers in
    ; red zone in the local stack
    mov QWORD PTR [rsp-40], rsi
    mov QWORD PTR [rsp-32], rdx
    mov QWORD PTR [rsp-16], r8
    mov QWORD PTR [rsp-24], rcx
    mov esi, 8
    mov QWORD PTR [rsp-64], rax
    lea rax, [rsp-48]
    mov QWORD PTR [rsp-8], r9
    mov DWORD PTR [rsp-72], 8
    lea rdx, [rsp+8]
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
By the way, a similar usage of the Shadow Space is also considered here: 6.1.8 on page 739.

Using pointer to the first function argument

The example can be rewritten without va_arg macro:

```c
#include <stdio.h>

int arith_mean(int v, ...) {
    int *i=&v;
    int sum=*i, count=1;
    i++;
    while(1) {
        if (*((i)==-1)) // terminator
```
break;
    sum=sum+(*i);
    count++;
    i++;
}
return sum/count;
}
int main()
{
    printf("%d\n", arith_mean (1, 2, 7, 10, 15, -1 /* terminator */));
    // test: https://www.wolframalpha.com/input/?i=mean(1,2,7,10,15)
}

In other words, if an argument set is array of words (32-bit or 64-bit), we just enumerate array elements starting at first one.

### 3.15.2 `vprintf()` function case

Many programmers define their own logging functions which take a printf-like format string + a variable number of arguments.

Another popular example is the `die()` function, which prints some message and exits.

We need some way to pack input arguments of unknown number and pass them to the `printf()` function. But how?

That’s why there are functions with “v” in name.

One of them is `vprintf()`: it takes a format-string and a pointer to a variable of type `va_list`:

```c
#include <stdlib.h>
#include <stdarg.h>

void die (const char * fmt, ...)
{
    va_list va;
    va_start (va, fmt);
    vprintf (fmt, va);
    exit(0);
}
```

By closer examination, we can see that `va_list` is a pointer to an array. Let’s compile:

#### Listing 3.61: Optimizing MSVC 2010

```asm
_fmt$ = 8
_die PROC
    ; load 1st argument (format-string)
    mov  ecx, DWORD PTR _fmt$[esp-4]
    ; get pointer to the 2nd argument
    lea  eax, DWORD PTR _fmt$[esp]
    push  eax
    push  ecx
    call _vprintf
    add  esp, 8
    push  0
    call _exit
$LN3@die:
    int  3
_die ENDP
```

We see that all our function does is just taking a pointer to the arguments and passing it to `vprintf()`, and that function is treating it like an infinite array of arguments!

#### Listing 3.62: Optimizing MSVC 2012 x64

```asm
fmt$ = 48
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
die PROC
    ; save first 4 arguments in Shadow Space
    mov    QWORD PTR [rsp+8], rcx
    mov    QWORD PTR [rsp+16], rdx
    mov    QWORD PTR [rsp+24], r8
    mov    QWORD PTR [rsp+32], r9
    sub    rsp, 40
    lea    rdx, QWORD PTR fmt$[rsp+8]; pass pointer to the 1st argument
    ; RCX here is still points to the 1st argument (format-string) of die()
    ; so vprintf() will take it right from RCX
    call   vprintf
    xor    ecx, ecx
    call   exit
    int    3
die    ENDP

3.15.3 Pin case

It’s interesting to note how some functions from Pin DBI\textsuperscript{16} framework takes number of arguments:

\[
\text{INS\_InsertPredicatedCall}(\ins, \text{IPOINT\_BEFORE}, \text{AFUNPTR}\text{RecordMemRead},\]
\[
\text{IARG\_INST\_PTR},\]
\[
\text{IARG\_MEMORYOP\_EA}, \text{memOp,}\]
\[
\text{IARG\_END});
\]

(pinatrace.cpp)

And this is how INS_InsertPredicatedCall() function is declared:

\[
\text{extern } \text{VOID } \text{INS\_InsertPredicatedCall}(\ins, \text{IPOINT ipoint, AFUNPTR funptr, } ...);\]

(pin\_client.PH)

Hence, constants with names starting with IARG_ are some kinds of arguments to the function, which are handled inside of INS_InsertPredicatedCall(). You can pass as many arguments, as you need. Some commands has additional argument(s), some are not. Full list of arguments: https://software.intel.com/sites/landingpage/pintool/docs/58423/Pin/html/group__INST__ARGS.html. And it has to be a way to detect an end of arguments list, so the list must be terminated with IARG_END constant, without which, the function will (try to) handle random noise in the local stack, treating it as additional arguments.

Also, in [Brian W. Kernighan, Rob Pike, Practice of Programming, (1999)] we can find a nice example of C/C++ routines very similar to pack/unpack\textsuperscript{17} in Python.

3.15.4 Format string exploit

It’s a popular mistake, to write printf(string) instead of puts(string) or printf("%s", string). If the attacker can put his/her own text into string, he/she can crash process, or get insight into variables in the local stack.

Take a look at this:

```
#include <stdio.h>

int main()
{
    char *s1="hello";
    char *s2="world";
    char buf[128];

    // do something mundane here
    strcpy (buf, s1);
    strcpy (buf, " ");
    strcpy (buf, s2);
```

\textsuperscript{16}Dynamic Binary Instrumentation
\textsuperscript{17}https://docs.python.org/3/library/struct.html

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
printf("%s");
};

Please note, that printf() has no additional arguments besides single format string.

Now let's imagine, that was the attacker who put %s string into the last printf() first arguments. I compile this example using GCC 5.4.0 on x86 Ubuntu, and the resulting executable prints “world” string if it gets executed!

If I turn optimization on, printf() outputs some garbage, though—probably, strcpy() calls has been optimized and/or local variables as well. Also, result will be different for x64 code, different compiler, OS, etc.

Now, let’s say, attacker could pass the following string to printf() call: %x %x %x %x %x. In may case, output is: “80485c6 b7751b48 1 0 80485c0” (these are just values from local stack). You see, there are 1 and 0 values, and some pointers (first is probably pointer to “world” string). So if the attacker passes %s %s %s %s string, the process will crash, because printf() treats 1 and/or 0 as pointer to string, tries to read characters from there and fails.

Even worse, there could be sprintf (buf, string) in code, where buf is a buffer in the local stack with size of 1024 bytes or so, attacker can craft string in such a way that buf will be overflown, maybe even in a way that would lead to code execution.

Many popular and well-known software was (or even still) vulnerable:

QuakeWorld went up, got to around 4000 users, then the master server exploded. Disrupter and cohorts are working on more robust code now.
If anyone did it on purpose, how about letting us know... (It wasn’t all the people that tried %s as a name)

(John Carmack’s .plan file, 17-Dec-199618)

Nowadays, almost all decent compilers warn about this.

Another problem is the lesser known %n printf() argument: whenever printf() reaches it in a format string, it writes the number of characters printed so far into the corresponding argument: http://stackoverflow.com/questions/3401156/what-is-the-use-of-the-n-format-specifier-in-c. Thus, an attacker could zap local variables by passing many %n commands in format string.

3.16 Strings trimming

A very common string processing task is to remove some characters at the start and/or at the end.

In this example, we are going to work with a function which removes all newline characters (\r\n) from the end of the input string:

```
#include <stdio.h>
#include <string.h>

char* str_trim (char *s)
{
    char c;
    size_t str_len;

    // work as long as \r or \n is at the end of string
    // stop if some other character there or its an empty string
    // (at start or due to our operation)
    for (str_len=strlen(s); str_len>0 && (c=s[str_len-1]); str_len--)
    {
        if (c=='\r' || c=='\n')
            s[str_len-1]=0;
        else
```

18https://github.com/ESWAT/john-carmack-plan-archive/blob/33ae52fdba46aa0d1abfed6fc7598233748541c0/by_day/johnc_plan_19961217.txt
19Carriage Return (13 or \r in C/C++)
20Line Feed (10 or \n in C/C++)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
break;
    return s;
};

int main()
{
   // test
   // strdup() is used to copy text string into data segment,
   // because it will crash on Linux otherwise,
   // where text strings are allocated in constant data segment,
   // and not modifiable.

   printf ("[%s]\n", str_trim (strdup("")));
   printf ("[%s]\n", str_trim (strdup("n")));
   printf ("[%s]\n", str_trim (strdup("r")));
   printf ("[%s]\n", str_trim (strdup("\n")));
   printf ("[%s]\n", str_trim (strdup("test1\n")));
   printf ("[%s]\n", str_trim (strdup("test2\n")));
   printf ("[%s]\n", str_trim (strdup("test3\n\n")));
   printf ("[%s]\n", str_trim (strdup("test4\n")));
   printf ("[%s]\n", str_trim (strdup("test5\r")));
   printf ("[%s]\n", str_trim (strdup("test6\r\r")));
}

The input argument is always returned on exit, this is convenient when you want to chain string processing functions, like it has done here in the main() function.

The second part of for() (str_len>0 && (c=s[str_len-1])) is the so called “short-circuit” in C/C++ and is very convenient [Dennis Yurichev, C/C++ programming language notes1.3.8].

The C/C++ compilers guarantee an evaluation sequence from left to right.
So if the first clause is false after evaluation, the second one is never to be evaluated.

### 3.16.1 \textit{x64: Optimizing MSVC 2013}

**Listing 3.63: Optimizing MSVC 2013 x64**

```assembly
s$ = 8
str trim PROC
   ; RCX is the first function argument and it always holds pointer to the string
   ; mov   rdx, rcx
   ; this is strlen() function inlined right here:
   ; set RAX to 0xFFFFFFFFFFFFFFFF (-1)
   or    rax, -1
$L14@str trim:
   inc   rax
   cmp   BYTE PTR [rcx+rax], 0
   jne   SHORT $L14@str trim
   ; is the input string length zero? exit then:
   test  rax, rax
   je    SHORT $LN15@str trim
   ; RAX holds string length
   dec   rcx
   ; RCX = s-1
   mov   r8d, 1
   add   rcx, rax
   ; RCX = s-1+strlen(s), i.e., this is the address of the last character in the string
   sub   r8, rdx
   ; R8 = 1-s
$L6@str trim:
   ; load the last character of the string:
   ; jump, if its code is 13 or 10:
   movzx  eax, BYTE PTR [rcx]
   cmp    al, 13
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
First, MSVC inlined the strlen() function code, because it concluded this is to be faster than the usual strlen() work + the cost of calling it and returning from it. This is called inlining: 3.12 on page 514.

The first instruction of the inlined strlen() is
OR RAX, 0xFFFFFFFFFFFFFFFF.

MSVC often uses OR instead of MOV RAX, 0xFFFFFFFFFFFFFFFF, because resulting opcode is shorter.

And of course, it is equivalent: all bits are set, and a number with all bits set is −1 in two’s complement arithmetic: 2.2 on page 458.

Why would the −1 number be used in strlen(), one might ask. Due to optimizations, of course. Here is the code that MSVC generated:

```
Listing 3.64: Inlined strlen() by MSVC 2013 x64

; RCX = pointer to the input string
; RAX = current string length
or  rax, -1
label:
  inc  rax
  cmp  BYTE PTR [rcx+rax], 0
  jne  SHORT label
; RAX = string length
```

Try to write shorter if you want to initialize the counter at 0! OK, let’s try:

```
Listing 3.65: Our version of strlen()

; RCX = pointer to the input string
; RAX = current string length
xor  rax, rax
label:
  cmp  byte ptr [rcx+rax], 0
  jz   exit
  inc  rax
  jmp  label
exit:
; RAX = string length
```

We failed. We have to use additional JMP instruction!

So what the MSVC 2013 compiler did is to move the INC instruction to the place before the actual character loading.

If the first character is 0, that’s OK, RAX is 0 at this moment, so the resulting string length is 0.

The rest in this function seems easy to understand.

### 3.16.2 x64: Non-optimizing GCC 4.9.1

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
str_trim:
    push rbp
    mov rbp, rsp
    sub rsp, 32
    mov QWORD PTR [rbp-24], rdi

; for() first part begins here
    mov rax, QWORD PTR [rbp-24]
    mov rdi, rax
    call strlen
    mov QWORD PTR [rbp-8], rax ; str_len

; for() first part ends here
    jmp .L2

; for() body begins here
.L5:
    cmp BYTE PTR [rbp-9], 13 ; c=='\r'?
    je .L3
    cmp BYTE PTR [rbp-9], 10 ; c=='\n'?
    jne .L4

.L3:
    mov rax, QWORD PTR [rbp-8] ; str_len
    lea rdx, [rax-1] ; EDX=str_len-1
    mov rax, QWORD PTR [rbp-24] ; s
    add rax, rdx ; RAX=s+str_len-1
    mov BYTE PTR [rax], 0 ; s[\str_len-1]=0

; for() body ends here
    for() third part begins here
    sub QWORD PTR [rbp-8], 1 ; str_len--
    for() third part ends here
.L2:
    for() second part begins here
    cmp QWORD PTR [rbp-8], 0 ; str_len==0?
    je .L4 ; exit then

; check second clause, and load "c"
    mov rax, QWORD PTR [rbp-8] ; RAX=str_len
    lea rdx, [rax-1] ; RDX=str_len-1
    mov rax, QWORD PTR [rbp-24] ; RAX=s
    add rax, rdx ; RAX=s+str_len-1
    movzx eax, BYTE PTR [rax] ; AL=s[\str_len-1]
    mov BYTE PTR [rbp-9], al ; store loaded char into "c"
    cmp BYTE PTR [rbp-9], 0 ; is it zero?
    jne .L5 ; yes? exit then

; for() second part ends here
.L4: ; return "s"
    mov rax, QWORD PTR [rbp-24]
    leave
    ret

Comments are added by the author of the book.

After the execution of str_len(), the control is passed to the L2 label, and there two clauses are checked, one after another.

The second will never be checked, if the first one (str_len==0) is false (this is “short-circuit”).

Now let’s see this function in short form:

- First for() part (call to strlen())
  - goto L2
- L5: for() body. goto exit, if needed
  - for() third part (decrement of str_len)
- L2: for() second part: check first clause, then second. goto loop body begin or exit.
- L4: // exit
- return s

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.16.3 x64: Optimizing GCC 4.9.1

str_trim:

push rbx
mov rbx, rdi
; RBX will always be "s"
call strlen
; check for str_len==0 and exit if so
test rax, rax
je .L9
lea rdx, [rax-1]
; RDX will always contain str_len-1 value, not str_len
; so RDX is more like buffer index variable
lea rsi, [rbx+rdx]; RSI=s+str_len-1
movzx ecx, BYTE PTR [rsi]; load character
test cl, cl
je .L9 ; exit if its zero
cmp cl, 10
je .L4 ; exit if its not \n and not \r
je .L9

.L4:
; this is weird instruction. we need RSI=s-1 here.
; its possible to get it by MOV RSI, EBX / DEC RSI
; but this is two instructions instead of one
sub rsi, rax
; RSI = s+str_len-1-str_len = s-1
main loop begin
.L12:

test rdx, rdx
; store zero at address s-1+str_len-1+1 = s-1+str_len = s+str_len-1
mov BYTE PTR [rsi+1+rdx], 0
; check for str_len-1==0. exit if so.
je .L9
sub rdx, 1 ; equivalent to str_len--
; load next character at address s+str_len-1
movzx ecx, BYTE PTR [rbx+rdx]
test cl, cl ; is it zero? exit then
je .L9
cmp cl, 10 ; is it \n? 
je .L12
cmp cl, 13 ; is it \r? 
je .L12

.L9:
; return "s"
mov rax, rbx
pop rbx
ret

Now this is more complex.
The code before the loop's body start is executed only once, but it has the CR/LF characters check too!
What is this code duplication for?
The common way to implement the main loop is probably this:

- (loop start) check for CR/LF characters, make decisions
- store zero character

But GCC has decided to reverse these two steps.

Of course, store zero character cannot be first step, so another check is needed:

- workout first character. match it to CR/LF, exit if character is not CR/LF
- (loop begin) store zero character
- check for CR/LF characters, make decisions

Now the main loop is very short, which is good for latest CPUs.
The code doesn’t use the str_len variable, but str_len-1. So this is more like an index in a buffer.
Apparently, GCC notices that the \texttt{str\_len-1} statement is used twice. So it’s better to allocate a variable which always holds a value that’s smaller than the current string length by one, and decrement it (this is the same effect as decrementing the \texttt{str\_len} variable).

### 3.16.4 ARM64: Non-optimizing GCC (Linaro) 4.9

This implementation is straightforward:

\begin{verbatim}
str\_trim:
    stp  x29, x30, [sp, -48]!
    add x29, sp, 0
    str x0, [x29,24]     ; copy input argument into local stack
    ldr x0, [x29,24]     ; s
    bl  strlen
    str x0, [x29,40]     ; str\_len variable in local stack
    b .L2

; main loop begin
.L5:
    ldrb w0, [x29,39]
    cmp w0, 13           ; is it '\r'?
    beq .L3
    ldrb w0, [x29,39]
    cmp w0, 10           ; is it '\n'?
    bne .L4
    cmp w0, w0            ; goto exit if it is not
    bne .L4
    ; W0=c
    strb wzr, [x0]        ; write byte at s+str\_len-1

    ; decrement str\_len:
    ldr x0, [x29,40]
    sub x0, x0, #1
    ldr x1, [x29,24]
    add x0, x1, x0
    ldr x0, [x29,40]
    sub x0, x0, #1
    ldr x1, [x29,24]
    add x0, x1, x0
    ldr x0, [x29,40]
    cmp x0, x0, xzr      ; goto exit then
    beq .L4
    ldr x0, [x29,40]
    sub x0, x0, #1
    ldr x1, [x29,24]
    add x0, x1, x0
    ldrb w0, [x0]         ; load byte at address s+str\_len-1 to W0
    strb w0, [x29,39]     ; store loaded byte to "c"
    ldrb w0, [x29,39]     ; reload it
    cmp w0, wzr           ; is it zero byte?
    bne .L5
    ; goto exit, if its zero or to L5 if its not

.L4:
\end{verbatim}

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.16.5 ARM64: Optimizing GCC (Linaro) 4.9

This is a more advanced optimization.

The first character is loaded at the beginning, and compared against 10 (the LF character).

Characters are also loaded in the main loop, for the characters after first one.

This is somewhat similar to the 3.16.3 on page 536 example.

Listing 3.67: Optimizing GCC (Linaro) 4.9

```assembly
str_trim:
    stp    x29, x30, [sp, -32]!
    add    x29, sp, 0
    str    x19, [sp,16]
    mov    x19, x0
    ; X19 will always hold value of "s"
    bl      strlen
    ; X0=str_len
    cbz    x0, .L9 ; goto L9 (exit) if str_len==0
    sub    x1, x0, #1
    ; X1=X0-1= str_len-1
    add    x3, x19, x1
    ; X3=X19+X1=s+str_len-1
    ldrb   w2, [x19,x1] ; load byte at address X19+X1=s+str_len-1
    ; W2=loaded character
    cbz    w2, .L9 ; is it zero? jump to exit then
    cmp    w2, 10 ; is it '\n'?  
    bne    .L15
    .L12:
    ; main loop body. loaded character is always 10 or 13 at this moment!
    sub    x2, x1, x0
    ; X2=X1-X0= str_len-1- str_len=-1
    add    x2, x3, x2
    ; X2=X3+X2=s+str_len-1+(-1)=s+str_len-2
    strb   wzr, [x2,1] ; store zero byte at address s+str_len-2+1=s+str_len-1
    cbz    x1, .L9 ; str_len-1==0? goto exit, if so
    sub    x1, x1, #1 ; str_len--
    ldrb   w2, [x19,x1] ; load next character at address X19+X1=s+str_len-1
    cmp    w2, 10 ; is it '\n'?
    cbz    w2, .L9 ; jump to exit, if its zero
    beq    .L12 ; jump to begin loop, if its '\n'
    .L15:
    cmp    w2, 13 ; is it '\r'?
    beq    .L12 ; yes, jump to the loop body begin
    .L9:
    ; return "s"
    mov    x0, x19
    ldr    x19, [sp,16]
    ldp    x29, x30, [sp], 32
    ret
```

3.16.6 ARM: Optimizing Keil 6/2013 (ARM mode)

And again, the compiler took advantage of ARM mode’s conditional instructions, so the code is much more compact.

Listing 3.68: Optimizing Keil 6/2013 (ARM mode)

```assembly
str_trim PROC
    PUSH {r4,lr}

    ; return s
    ldr    x0, [x29,24]
    ldp    x29, x30, [sp], 48
    ret
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.16.7 ARM: Optimizing Keil 6/2013 (Thumb mode)

There are less conditional instructions in Thumb mode, so the code is simpler.

But there are is really weird thing with the 0x20 and 0x1F offsets (lines 22 and 23). Why did the Keil compiler do so? Honestly, it's hard to say.

It has to be a quirk of Keil’s optimization process. Nevertheless, the code works correctly.

Listing 3.69: Optimizing Keil 6/2013 (Thumb mode)
Listing 3.70: Optimizing GCC 4.4.5 (IDA)

str_trim:
; IDA is not aware of local variable names, we gave them manually:
saved_GP      = -0x10
saved_S0     = -8
saved_RA     = -4

    lui   $gp, (__gnu_local_gp >> 16)
    addiu $sp, -0x20
    la    $gp, (__gnu_local_gp & 0xFFFF)
    sw    $ra, 0x20+saved_RA($sp)
    sw    $s0, 0x20+saved_S0($sp)
    sw    $gp, 0x20+saved_GP($sp)
; call strlen(). input string address is still in $a0, strlen() will take it from there:
    lw    $t9, (strlen & 0xFFFF)($gp)
    or    $at, $zero ; load delay slot, NOP
    jalr  $t9 ; input string address is still in $a0, put it to $s0:
    move  $s0, $a0 ; branch delay slot
; result of strlen() (i.e, length of string) is in $v0 now
; jump to exit if $v0==0 (i.e., if length of string is 0):
    beqz  $v0, exit
    or    $at, $zero ; branch delay slot, NOP
    addiu $a1, $v0, -1
; $a1 = $v0-1 = strlen-1
    addu $a1, $s0, $a1
; $a1 = input string address + $a1 = s+strlen-1
; load byte at address $a1:
    lb    $a0, 0($a1)
    or    $at, $zero ; load delay slot, NOP
; loaded byte is zero? jump to exit if its so:
    beqz  $a0, exit
    or    $at, $zero ; branch delay slot, NOP
    addiu $v1, $v0, -2
; $v1 = strlen-2
    addu $v1, $s0, $v1
; skip loop body:
    li    $a2, 0xD
    li    $a3, 0xA ; branch delay slot
loc_5c:
; load next byte from memory to $a0:
    lb    $a0, 0($v1)
    move  $a1, $v1
; $a1=s+strlen-2
; jump to exit if loaded byte is zero:
    beqz  $a0, exit
; decrement strlen:
    addiu $v1, -1 ; branch delay slot
loc_6c:
; at this moment, $a0=loaded byte, $a2=0xD (CR symbol) and $a3=0xA (LF symbol)
; loaded byte is CR? jump to loc_7c then:
    beq    $a0, $a2, loc_7c
    addiu  $v0, -1 ; branch delay slot
; loaded byte is LF? jump to exit if its not LF:
    bne   $a0, $a3, exit
    or    $at, $zero ; branch delay slot, NOP
loc_7c:
; loaded byte is CR at this moment
; jump to loc_5c (loop body begin) if strlen (in $v0) is not zero:
    bnez  $v0, loc_5c
; simultaneously, store zero at that place in memory:
    sb    $zero, 0($a1) ; branch delay slot
; "exit" label was named by me manually:
exit:
    lw    $ra, 0x20+saved_RA($sp)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Another very popular function transforms a symbol from lower case to upper case, if needed:

```c
char toupper (char c)
{
    if(c=='a' && c<='z')
        return c-'a'+'A';
    else
        return c;
}
```

The 'a'+'A' expression is left in the source code for better readability, it will be optimized by compiler, of course. The ASCII code of “a” is 97 (or 0x61), and 65 (or 0x41) for “A”. The difference (or distance) between them in the ASCII table is 32 (or 0x20).

For better understanding, the reader may take a look at the 7-bit standard ASCII table:

![7-bit ASCII table in Emacs](image)

### 3.17.1 x64

**Two comparison operations**

Non-optimizing MSVC is straightforward: the code checks if the input symbol is in \([97..122]\) range (or in \('[a'..'z']\) range) and subtracts 32 if it's true.

There are also some minor compiler artifact:

```plaintext
Listing 3.71: Non-optimizing MSVC 2013 (x64)
1  c$ = 8
2  toupper PROC
3    mov    BYTE PTR [rsp+8], cl
4    movsx  eax, BYTE PTR c$[rsp]
5    cmp    eax, 97
6    jl     SHORT $LN2@toupper
7    movsx  eax, BYTE PTR c$[rsp]
8    cmp    eax, 122
9    jg     SHORT $LN2@toupper
```

However, to be meticulous, there still could be compilers which can't optimize such expressions and will leave them right in the code.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
It’s important to notice that the input byte is loaded into a 64-bit local stack slot at line 3. All the remaining bits ([8..63]) are untouched, i.e., contain some random noise (you’ll see it in debugger).

All instructions operate only on byte-level, so it’s fine.

The last MOVSX instruction at line 15 takes the byte from the local stack slot and zero-extends it to an int 32-bit data type.

Non-optimizing GCC does mostly the same:

Listing 3.72: Non-optimizing GCC 4.9 (x64)

One comparison operation

Optimizing MSVC does a better job, it generates only one comparison operation:

Listing 3.73: Optimizing MSVC 2013 (x64)

We will now rewrite this in C/C++:

```c
int tmp = c - 97;
if (tmp > 25)
    return c;
else
    return c - 32;
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The tmp variable must be signed.

This makes two subtraction operations in case of a transformation plus one comparison. In contrast the original algorithm uses two comparison operations plus one subtracting.

Optimizing GCC is even better, it gets rid of the jumps (which is good: 2.10.1 on page 471) by using the CMOVcc instruction:

```
Listing 3.74: Optimizing GCC 4.9 (x64)

toupper:
    lea    edx, [rdi-97] ; 0x61
    lea    eax, [rdi-32] ; 0x20
    cmp    dl, 25
    cmova  eax, edi
    ret
```

At line 3 the code prepares the subtracted value in advance, as if the conversion will always happen. At line 5 the subtracted value in EAX is replaced by the untouched input value if a conversion is not needed. And then this value (of course incorrect) is dropped.

Advance subtracting is a price the compiler pays for the absence of conditional jumps.

### 3.17.2 ARM

Optimizing Keil for ARM mode also generates only one comparison:

```
Listing 3.75: Optimizing Keil 6/2013 (ARM mode)

toupper PROC
    SUB    r1, r0, #0x61
    CMP    r1, #0x19
    SUBLS  r0, r0, #0x20
    ANDLS  r0, r0, #0xff
    BX     lr
ENDP
```

The SUBLS and ANDLS instructions are executed only if the value in R1 is less than 0x19 (or equal). They also do the actual conversion.

Optimizing Keil for Thumb mode generates only one comparison operation as well:

```
Listing 3.76: Optimizing Keil 6/2013 (Thumb mode)

toupper PROC
    MOVS   r1, r0
    SUBS   r1, r1, #0x61
    CMP    r1, #0x19
    BHI    |L0.14|
    SUBS   r0, r0, #0x20
    LSLS   r0, r0, #24
    LSRS   r0, r0, #24
    |L0.14|
    BX     lr
ENDP
```

The last two LSLS and LSRS instructions work like AND reg, 0xFF: they are equivalent to the C/C++ expression \((i << 24) >> 24\).

Seems like that Keil for Thumb mode deduced that two 2-byte instructions are shorter than the code that loads the 0xFF constant into a register plus an AND instruction.

### GCC for ARM64

```
Listing 3.77: Non-optimizing GCC 4.9 (ARM64)

toupper:
    sub    sp, sp, #16
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.17.3 Using bit operations

Given the fact that 5th bit (counting from 0th) is always present after the check, subtracting is merely clearing this sole bit, but the very same effect can be achieved with ANDing (2.5 on page 463).

Even simpler, with XOR-ing:

```c
char toupper (char c)
{
    if(c=='a' && c<='z')
        return c^0x20;
    else
        return c;
}
```

The code is close to what the optimized GCC has produced for the previous example (3.74 on the preceding page):

```
Listing 3.79: Optimizing GCC 5.4 (x86)
toupper:
    mov    edx, DWORD PTR [esp+4]
    lea    ecx, [edx-97]
    mov    eax, edx
    xor    eax, 32
    cmp    cl, 25
    cmova  eax, edx
    ret
```

...but XOR is used instead of SUB.

Flipping 5th bit is just moving a cursor in ASCII table up and down by two rows.

Some people say that lowercase/uppercase letters has been placed in the ASCII table in such a way deliberately, because:
Very old keyboards used to do Shift just by toggling the 32 or 16 bit, depending on the key; this is why the relationship between small and capital letters in ASCII is so regular, and the relationship between numbers and symbols, and some pairs of symbols, is sort of regular if you squint at it.

Therefore, we can write this piece of code, which just flips the case of letters:

```c
#include <stdio.h>

char flip (char c)
{
    if((c>='a' && c<='z') || (c>='A' && c<='Z'))
        return c^0x20;
    else
        return c;
}

int main()
{
    // will produce "hELLO, WORLD!"
    for (char *s="Hello, world!"; *s; s++)
        printf("%c", flip(*s));
}
```

### 3.17.4 Summary

All these compiler optimizations are very popular nowadays and a practicing reverse engineer usually sees such code patterns often.

### 3.18 Obfuscation

The obfuscation is an attempt to hide the code (or its meaning) from reverse engineers.

#### 3.18.1 Text strings

As we know from ([5.4 on page 703](703)), text strings may be really helpful.

Programmers who are aware of this try to hide them, making it impossible to find the string in IDA or any hex editor.

Here is the simplest method.

This is how the string can be constructed:

```assembly
mov byte ptr [ebx], 'h'
mov byte ptr [ebx+1], 'e'
mov byte ptr [ebx+2], 'l'
mov byte ptr [ebx+3], 'l'
mov byte ptr [ebx+4], 'o'
mov byte ptr [ebx+5], ','
mov byte ptr [ebx+6], 'w'
mov byte ptr [ebx+7], 'o'
mov byte ptr [ebx+8], 'r'
mov byte ptr [ebx+9], 'l'
mov byte ptr [ebx+10], 'd'
```

The string can also be compared with another one like this:
In both cases, it is impossible to find these strings straightforwardly in a hex editor.

By the way, this is a way to work with the strings when it is impossible to allocate space for them in the data segment, for example in a PIC\textsuperscript{22} or in shellcode.

Another method is to use \texttt{sprintf()} for the construction:

\begin{verbatim}
sprintf(buf, "\%s\%c\%c\%s", "hel","l","o w","o","rld");
\end{verbatim}

The code looks weird, but as a simple anti-reversing measure, it may be helpful.

Text strings may also be present in encrypted form, then every string usage is to be preceded by a string decrypting routine. For example: \textbf{8.5.2 on page 822}.

\section*{3.18.2 Executable code}

\subsection*{Inserting garbage}

Executable code obfuscation implies inserting random garbage code between real one, which executes but does nothing useful.

A simple example:

\begin{verbatim}
add eax, ebx
mul ecx
\end{verbatim}

\begin{verbatim}
xor esi, 011223344h ; garbage
add esi, eax ; garbage
add eax, ebx ; garbage
mov edx, eax ; garbage
shl edx, 4 ; garbage
mul ecx
xor esi, ecx ; garbage
\end{verbatim}

Here the garbage code uses registers which are not used in the real code (ESI and EDX). However, the intermediate results produced by the real code may be used by the garbage instructions for some extra mess—why not?

\subsection*{Replacing instructions with bloated equivalents}

\begin{itemize}
\item \texttt{MOV} \texttt{op1, op2} can be replaced by the \texttt{PUSH op2 / POP op1} pair.
\item \texttt{JMP label} can be replaced by the \texttt{PUSH label / RET} pair. \texttt{IDA} will not show the references to the label.
\item \texttt{CALL label} can be replaced by the following instructions triplet: \texttt{PUSH label_after_CALL_instruction / PUSH label / RET}.
\item \texttt{PUSH op} can also be replaced with the following instructions pair: \texttt{SUB ESP, 4 (or 8) / MOV [ESP], op}.
\end{itemize}

\textsuperscript{22}Position Independent Code
Always executed/never executed code

If the developer is sure that ESI at always 0 at that point:

```
    mov esi, 1
    ... ; some code not touching ESI
    dec esi
    ... ; some code not touching ESI
    cmp esi, 0
    jz    real_code
    ; fake luggage
real_code:
```

The reverse engineer needs some time to get into it.

This is also called an opaque predicate.

Another example (and again, the developer is sure that ESI is always zero):

```
    add eax, ebx ; real code
    mul ecx ; real code
    add eax, esi ; opaque predicate. XOR, AND or SHL, etc, can be here instead of ADD.
```

Making a lot of mess

```
instruction 1
instruction 2
instruction 3
```

Can be replaced with:

```
begin:          jmp   ins1_label
    jmp   ins3_label
    jmp   exit:

ins1_label:    instruction 1
    jmp   ins2_label
exit:
```

Using indirect pointers

```
dummy_data1  db  100h dup (0)
message1     db  'hello world',0

dummy_data2  db  200h dup (0)
message2     db  'another message',0

func           proc
    mov     eax, offset dummy_data1 ; PE or ELF reloc here
    add     eax, 100h
    push    eax
    call    dump_string
    ...    mov     eax, offset dummy_data2 ; PE or ELF reloc here
    add     eax, 200h
    push    eax
    call    dump_string
    ...    jmp   ins1_label
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
IDA will show references only to dummy_data1 and dummy_data2, but not to the text strings. Global variables and even functions may be accessed like that.

3.18.3 Virtual machine / pseudo-code

A programmer can construct his/her own PL or ISA and interpreter for it. (Like the pre-5.0 Visual Basic, .NET or Java machines). The reverse engineer will have to spend some time to understand the meaning and details of all of the ISA’s instructions.

He/she will also have to write a disassembler/decompiler of some sort.

3.18.4 Other things to mention

My own (yet weak) attempt to patch the Tiny C compiler to produce obfuscated code: http://go.yurichev.com/17220.

Using the MOV instruction for really complicated things: [Stephen Dolan, mov is Turing-complete, (2013)]

3.18.5 Exercise

- http://challenges.re/29

3.19 C++

3.19.1 Classes

A simple example

Internally, the representation of C++ classes is almost the same as the structures.

Let’s try an example with two variables, two constructors and one method:

```c++
#include <stdio.h>

class c
{
private:
  int v1;
  int v2;
public:
  c() // default ctor
  {
    v1=667;
    v2=999;
  };
  c(int a, int b) // ctor
  {
    v1=a;
    v2=b;
  };
  void dump()
  {
    printf("%d %d\n", v1, v2);
  };
};
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!

23 Also available as http://www.cl.cam.ac.uk/~sd601/papers/mov.pdf
int main()
{
    class c c1;
    class c c2(5,6);
    c1.dump();
    c2.dump();
    return 0;
};

MSVC: x86

Here is how the main() function looks like, translated into assembly language:

Listing 3.82: MSVC

_c2$ = -16 ; size = 8
_c1$ = -8 ; size = 8
_main PROC
    push ebp
    mov ebp, esp
    sub esp, 16
    lea ecx, DWORD PTR _c1$[ebp]
    call ??0c@@QAE@XZ ; c::c
    push 6
    push 5
    lea ecx, DWORD PTR _c2$[ebp]
    call ??0c@@QAE@HH@Z ; c::c
    lea ecx, DWORD PTR _c1$[ebp]
    call ?dump@QAE@XZ ; c::dump
    lea ecx, DWORD PTR _c2$[ebp]
    call ?dump@QAE@XZ ; c::dump
    xor eax, eax
    mov esp, ebp
    pop ebp
    ret 0
_main ENDP

Here’s what’s going on. For each object (instance of class c) 8 bytes are allocated, exactly the size needed to store the 2 variables.

For c1 a default argumentless constructor ??0c@@QAE@XZ is called. For c2 another constructor ??0c@@QAE@HH@Z is called and two numbers are passed as arguments.

A pointer to the object (this in C++ terminology) is passed in the ECX register. This is called thiscall (3.19.1) — the method for passing a pointer to the object.

MSVC does it using the ECX register. Needless to say, it is not a standardized method, other compilers can do it differently, e.g., via the first function argument (like GCC).

Why do these functions have such odd names? That’s name mangling.

A C++ class may contain several methods sharing the same name but having different arguments—that is polymorphism. And of course, different classes may have their own methods with the same name.

Name mangling enable us to encode the class name + method name + all method argument types in one ASCII string, which is then used as an internal function name. That’s all because neither the linker, nor the DLL OS loader (mangled names may be among the DLL exports as well) knows anything about C++ or OOP.

The dump() function is called two times.

Now let’s see the constructors’ code:

Listing 3.83: MSVC

_this$ = -4 ; size = 4
??0c@@QAE@XZ PROC ; c::c, COMDAT

24 Object-Oriented Programming

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The constructors are just functions, they use a pointer to the structure in ECX, copying the pointer into their own local variable, however, it is not necessary.

From the C++ standard (C++11 12.1) we know that constructors are not required to return any values. In fact, internally, the constructors return a pointer to the newly created object, i.e., this.

Now the dump() method:

```
; _this$ = ecx
    push ebp
    mov ebp, esp
    push ecx
    mov DWORD PTR _this$[ebp], ecx
    mov eax, DWORD PTR _this$[ebp]
    mov DWORD PTR [eax], 667
    mov ecx, DWORD PTR _this$[ebp]
    mov DWORD PTR [ecx+4], 999
    mov eax, DWORD PTR _this$[ebp]
    mov esp, ebp
    pop ebp
    ret 0
??0__c@@QAE@XZ ; c::c

; _this$ = -4 ; size = 4
; _a$ = 8 ; size = 4
; _b$ = 12 ; size = 4
??0__c@@H@Z ; c::c, COMDAT
; _this$ = ecx
    push ebp
    mov ebp, esp
    push ecx
    mov DWORD PTR _this$[ebp], ecx
    mov eax, DWORD PTR _this$[ebp]
    mov edx, DWORD PTR _this$[ebp]
    mov eax, DWORD PTR _this$[ebp]
    mov DWORD PTR [edx+4], eax
    mov esp, ebp
    pop ebp
    ret 8
??0__c@@H@Z ; c::c
```

Simple enough: dump() takes a pointer to the structure that contains the two int’s from ECX, takes both values from it and passes them to printf().

The code is much shorter if compiled with optimizations (/Ox):

```
; _this$ = ecx
    push ebp
    mov ebp, esp
    push ecx
    mov DWORD PTR _this$[ebp], ecx
    mov eax, DWORD PTR _this$[ebp]
    mov DWORD PTR [eax], 667
    mov ecx, DWORD PTR _this$[ebp]
    mov DWORD PTR [ecx+4], 999
    mov eax, DWORD PTR _this$[ebp]
    mov esp, ebp
    pop ebp
    ret 0
??0__c@@QAE@XZ ; c::c
```
That’s all. The other thing we must note is that the *stack pointer* hasn’t been corrected with add esp, X after the constructor has been called. At the same time, the constructor has ret 8 instead of RET at the end.

This is all because the thiscall ([3.19.1 on page 549](#)) calling convention is used here, which together with the stdcall ([6.1.2 on page 733](#)) method offers the callee to correct the stack instead of the caller. The ret x instruction adds X to the value in ESP, then passes the control to the caller function.

See also the section about calling conventions ([6.1 on page 733](#)).

It also has to be noted that the compiler decides when to call the constructor and destructor—but we already know that from the C++ language basics.

**MSVC: x86-64**

As we already know, the first 4 function arguments in x86-64 are passed in RCX, RDX, R8 and R9 registers, all the rest—via the stack.

Nevertheless, the *this* pointer to the object is passed in RCX, the first argument of the method in RDX, etc. We can see this in the c(int a, int b) method internals:

```
??0c@@QAE@XZ PROC ; c::c, COMDAT
 ; _this$ = ecx
   mov eax, ecx
   mov DWORD PTR [eax], 667
   mov DWORD PTR [eax+4], 999
   ret 0
??0c@@QAE@XZ ENDP ; c::c
.a$ = 8 ; size = 4
.b$ = 12 ; size = 4
??0c@@QAE@HH@Z PROC ; c::c, COMDAT
 ; _this$ = ecx
   mov edx, DWORD PTR _b$[esp-4]
   mov eax, ecx
   mov ecx, DWORD PTR _a$[esp-4]
   mov DWORD PTR [eax], ecx
   mov DWORD PTR [eax+4], edx
   ret 8
??0c@@QAE@HH@Z ENDP ; c::c
??0c@@QAE@HH@Z PROC ; c::c
 ; _this$ = ecx
   mov eax, DWORD PTR [ecx+4]
   mov ecx, DWORD PTR [ecx]
   push eax
   push ecx
   push OFFSET ??_C@_07NJBDCIEC@?$CFd?$DL?5?$CFd?76?$AA@
   call printf
   add esp, 12
   ret 0
??0c@@QAE@HH@Z ENDP ; c::c
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
The int data type is still 32-bit in x64, so that is why 32-bit register parts are used here.

We also see JMP printf instead of RET in the dump() method, that hack we already saw earlier: 1.21.1 on page 156.

GCC: x86

It is almost the same story in GCC 4.4.1, with a few exceptions.

Listing 3.87: GCC 4.4.1

```
public main
main proc near

var_20 = dword ptr -20h
var_1C = dword ptr -1Ch
var_18 = dword ptr -18h
var_10 = dword ptr -10h
var_8 = dword ptr -8h

push ebp
mov ebp, esp
and esp, 0FFFFFFF0h
sub esp, 20h
lea eax, [esp+20h+var_8]
mov [esp+20h+var_20], eax
call _ZN1cC1Ev
mov [esp+20h+var_18], 6
mov [esp+20h+var_1C], 5
lea eax, [esp+20h+var_10]
mov [esp+20h+var_20], eax
call _ZN1cC1Eii
lea eax, [esp+20h+var_8]
mov [esp+20h+var_20], eax
call _ZN1c4dumpEv
lea eax, [esp+20h+var_10]
mov [esp+20h+var_20], eax
lea eax, [esp+20h+var_8]
mov [esp+20h+var_20], eax
call _ZN1c4dumpEv
lea eax, [esp+20h+var_10]
mov [esp+20h+var_20], eax
lea eax, [esp+20h+var_8]
mov [esp+20h+var_20], eax
lea eax, [esp+20h+var_10]
lea eax, [esp+20h+var_8]
imin
mov eax, 0
leave
retn
main endp
```

Here we see another name mangling style, specific to GNU. It can also be noted that the pointer to the object is passed as the first function argument—invisible to programmer, of course.

First constructor:

```
_public _ZN1cC1Ev ; weak
_ZN1cC1Ev proc near ; CODE XREF: main+10
```

---

25Apparantly, for easier porting of 32-bit C/C++ code to x64.

26There is a good document about the various name mangling conventions in different compilers: [Agner Fog, Calling conventions (2015)].

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
arg_0 = dword ptr 8
push ebp
mov ebp, esp
mov eax, [ebp+arg_0]
mov dword ptr [eax], 667
mov eax, [ebp+arg_0]
mov dword ptr [eax+4], 999
pop ebp
ret

ZN1cC1Ev endp

It just writes two numbers using the pointer passed in the first (and only) argument.

Second constructor:

Second constructor:

public _ZN1cC1Eii
_ZN1cC1Eii proc near
arg_0 = dword ptr 8
arg_4 = dword ptr 0Ch
arg_8 = dword ptr 10h
push ebp
mov ebp, esp
mov eax, [ebp+arg_0]
mov edx, [eax+4]
mov eax, [ebp+arg_0]
mov edx, [ebp+arg_8]
mov [eax+4], edx
pop ebp
ret

Z1nC1Eii endp

This is a function, the analog of which can look like this:

void ZN1cC1Eii (int *obj, int a, int b)
{
    *obj=a;
    *(obj+1)=b;
};

…and that is completely predictable.

Now the dump() function:

public _ZN1c4dumpEv
_ZN1c4dumpEv proc near
var_18 = dword ptr -18h
var_14 = dword ptr -14h
var_10 = dword ptr -10h
arg_0 = dword ptr 8
push ebp
mov ebp, esp
sub esp, 18h
mov eax, [ebp+arg_0]
mov edx, [eax+4]
mov eax, [ebp+arg_0]
mov eax, [eax]
mov [esp+18h+var_10], edx
mov [esp+18h+var_14], eax
mov [esp+18h+var_18], offset aDD ; "%d; %d\n"
call _printf
leave
ret

_ZN1c4dumpEv endp

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This function in its *internal representation* has only one argument, used as pointer to the object (*this*).

This function could be rewritten in C like this:

```c
voidZN1c4dumpEv(int*obj)
{
    printf("%d; %d\n", *obj, *(obj+1));
}
```

Thus, if we base our judgment on these simple examples, the difference between MSVC and GCC is the style of the encoding of function names (*name mangling*) and the method for passing a pointer to the object (via the ECX register or via the first argument).

**GCC: x86-64**

The first 6 arguments, as we already know, are passed in the RDI, RSI, RDX, RCX, R8 and R9 ([Michael Matz, Jan Hubicka, Andreas Jaeger, Mark Mitchell, *System V Application Binary Interface. AMD64 Architecture Processor Supplement, (2013)*] 27) registers, and the pointer to *this* via the first one (RDI) and that is what we see here. The int data type is also 32-bit here.

The JMP instead of RET *hack* is also used here.

```
Listing 3.88: GCC 4.4.6 x64

; default ctor
ZN1cC2Ev:
    mov DWORD PTR [rdi], 667
    mov DWORD PTR [rdi+4], 999
    ret

; c(int a, int b)
ZN1cC2Eii:
    mov DWORD PTR [rdi], esi
    mov DWORD PTR [rdi+4], edx
    ret

; dump()
ZN1c4dumpEv:
    mov edx, DWORD PTR [rdi+4]
    mov esi, DWORD PTR [rdi]
    xor eax, eax
    mov edi, OFFSET FLAT:.LC0 ; "%d; %d\n"
    jmp printf
```

**Class inheritance**

Inherited classes are similar to the simple structures we already discussed, but extended in inheritable classes.

Let’s take this simple example:

```c
#include <stdio.h>
classobject
{
public:
    intcolor;
    object(){};
    object(intcolor) {this->color=color;};
    voidprint_color() {printf("color=\%d\n",color);};
};
```

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
class box: public object
{
    private:
        int width, height, depth;
    public:
        box(int color, int width, int height, int depth)
        {
            this->color=color;
            this->width=width;
            this->height=height;
            this->depth=depth;
        }
        void dump()
        {
            printf("this is a box. color=%d, width=%d, height=%d, depth=%d
", color, width, height, depth);
        }
};

class sphere: public object
{
    private:
        int radius;
    public:
        sphere(int color, int radius)
        {
            this->color=color;
            this->radius=radius;
        }
        void dump()
        {
            printf("this is sphere. color=%d, radius=%d
", color, radius);
        }
};

int main()
{
    box b(1, 10, 20, 30);
    sphere s(2, 40);
    b.print_color();
    s.print_color();
    b.dump();
    s.dump();
    return 0;
};

Let's investigate the generated code of the dump() functions/methods and also object::print_color(), and see the memory layout for the structures-objects (for 32-bit code).

So, here are the dump() methods for several classes, generated by MSVC 2008 with /Ox and /Ob0 options.

Listing 3.89: Optimizing MSVC 2008 /Ob0

??_C@_09GCEDOLPA@color?$DN?$CFd76?$AA@ DB 'color=%d', 0aH, 00H ; 'string'
?print_color@object@@QAEXXZ PROC ; object::print_color, COMDAT
; _this$ = ecx
      mov  eax, DWORD PTR [ecx]
      push eax
; 'color=%d', 0aH, 00H
      push OFFSET ??_C@_09GCEDOLPA@color?$DN?$CFd76?$AA@
      call _printf
      add  esp, 8
      ret 0
?print_color@object@@QAEXXZ ENDP ; object::print_color

28The /Ob0 option stands for disabling inline expansion since function inlining can make our experiment harder.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Listing 3.90: Optimizing MSVC 2008 /Ob0

?dump@box@@QAEXXZ PROC ; box::dump, COMDAT  
; _this$ = ecx  
    mov eax, DWORD PTR [ecx+12]  
    mov edx, DWORD PTR [ecx+8]  
    push eax  
    mov eax, DWORD PTR [ecx+4]  
    mov ecx, DWORD PTR [ecx]  
    push edx  
    push eax  
    push ecx  
    ; 'this is a box. color=%d, width=%d, height=%d, depth=%d', 0aH, 00H  
    push OFFSET ??_C@OOG@NCNGAADL@this?5is?5box?4?5color?$DN?$CFd?0?5width?$DN?$CFd?0@  
    call _printf  
    add esp, 20  
    ret 0  
?dump@box@@QAEXXZ ENDP ; box::dump

Listing 3.91: Optimizing MSVC 2008 /Ob0

?dump@sphere@@QAEXXZ PROC ; sphere::dump, COMDAT  
; _this$ = ecx  
    mov eax, DWORD PTR [ecx+4]  
    mov ecx, DWORD PTR [ecx]  
    push eax  
    push ecx  
    ; 'this is sphere. color=%d, radius=%d', 0aH, 00H  
    push OFFSET ??_C@OF@EFEDJLDC@this?5is?5sphere?4?5color?$DN?$CFd?0?5radius@  
    call _printf  
    add esp, 12  
    ret 0  
?dump@sphere@@QAEXXZ ENDP ; sphere::dump

So, here is the memory layout:

(base class object)

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>int color</td>
</tr>
</tbody>
</table>

(inherited classes)

box:

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>int color</td>
</tr>
<tr>
<td>+0x4</td>
<td>int width</td>
</tr>
<tr>
<td>+0x8</td>
<td>int height</td>
</tr>
<tr>
<td>+0xC</td>
<td>int depth</td>
</tr>
</tbody>
</table>

sphere:

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>int color</td>
</tr>
<tr>
<td>+0x4</td>
<td>int radius</td>
</tr>
</tbody>
</table>

Let's see main() function body:

Listing 3.92: Optimizing MSVC 2008 /Ob0

PUBLIC _main
_TEXT SEGMENT  
_s$ = -24 ; size = 8  
_b$ = -16 ; size = 16  
_main PROC  
    sub esp, 24  
    push 30  
    push 20  
    push 10  
    push 1
The inherited classes must always add their fields after the base classes' fields, to make it possible for the base class methods to work with their own fields.

When the `object::print_color()` method is called, a pointer to both the `box` and `sphere` objects are passed as this, and it can work with these objects easily since the `color` field in these objects is always at the pinned address (at offset `+0x0`).

It can be said that the `object::print_color()` method is agnostic in relation to the input object type as long as the fields are pinned at the same addresses, and this condition is always true.

And if you create inherited class of the `box` class, the compiler will add the new fields after the `depth` field, leaving the `box` class fields at the pinned addresses.

Thus, the `box::dump()` method will work fine for accessing the `color`, `width`, `height` and `depths` fields, which are always pinned at known addresses.

The code generated by GCC is almost the same, with the sole exception of passing the `this` pointer (as it has been explained above, it is passed as the first argument instead of using the ECX register).

**Encapsulation**

Encapsulation is hiding the data in the private sections of the class, e.g. to allow access to them only from this class methods.

However, are there any marks in code the about the fact that some field is private and some other—not?

No, there are no such marks.

Let's try this simple example:

```c++
#include <stdio.h>

class box {
    private:
        int color, width, height, depth;
    public:
        box(int color, int width, int height, int depth) {
            this->color = color;
            this->width = width;
            this->height = height;
            this->depth = depth;
        }
        void dump() {
            printf("this is a box. color=%d, width=%d, height=%d, depth=%d\n", color, width, height, depth);
        }
};
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's compile it again in MSVC 2008 with /Ox and /Ob0 options and see the box::dump() method code:

```assembly
?dump@box@@QAEXXZ ; box::dump, COMDAT
    ;_this$ = ecx
    mov eax, DWORD PTR [ecx+12]
    mov edx, DWORD PTR [ecx+8]
    push eax
    mov eax, DWORD PTR [ecx+4]
    mov ecx, DWORD PTR [ecx]
    push edx
    push eax
    push ecx
    ; 'this is a box. color=%d, width=%d, height=%d, depth=%d', 0aH, 00H
    push OFFSET ??_C@_0DG@NCNGAADL@this?5is?5box?4?5color?$DN?$CFd?0?5width?$DN?$CFd?0@call_printf
    add esp, 20
    ret 0
?dump@box@@QAEXXZ ENDP ; box::dump
```

Here is a memory layout of the class:

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>int color</td>
</tr>
<tr>
<td>+0x4</td>
<td>int width</td>
</tr>
<tr>
<td>+0x8</td>
<td>int height</td>
</tr>
<tr>
<td>+0xC</td>
<td>int depth</td>
</tr>
</tbody>
</table>

All fields are private and not allowed to be accessed from any other function, but knowing this layout, can we create code that modifies these fields?

To do this we'll add the hack_oop_encapsulation() function, which is not going to compile if it looked like this:

```cpp
void hack_oop_encapsulation(class box * o)
{
    o->width=1; // that code can't be compiled:
        // "error C2248: 'box::width' : cannot access private member declared in class
    'box'=
};
```

Nevertheless, if we cast the box type to a pointer to an int array, and we modify the array of int-s that we have, we can succeed.

```cpp
void hack_oop_encapsulation(class box * o)
{
    unsigned int *ptr_to_object=reinterpret_cast<unsigned int*>(o);
    ptr_to_object[1]=123;
};
```

This function’s code is very simple—it can be said that the function takes a pointer to an array of int-s for input and writes 123 to the second int:

```assembly
?hack_oop_encapsulation@@YAXPAVbox@@Z PROC ; hack_oop_encapsulation
    mov eax, DWORD PTR _o$[esp-4]
    mov DWORD PTR [eax+4], 123
    ret 0
?hack_oop_encapsulation@@YAXPAVbox@@Z ENDP ; hack_oop_encapsulation
```

Let's check how it works:

```cpp
int main()
{
    box b(1, 10, 20, 30);
    b.dump();
    hack_oop_encapsulation(&b);
    b.dump();
    return 0;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's run:

```
this is a box. color=1, width=10, height=20, depth=30
this is a box. color=1, width=123, height=20, depth=30
```

We see that the encapsulation is just protection of class fields only in the compilation stage. The C++ compiler is not allowing the generation of code that modifies protected fields straightforwardly, nevertheless, it is possible with the help of dirty hacks.

**Multiple inheritance**

Multiple inheritance is creating a class which inherits fields and methods from two or more classes. Let's write a simple example again:

```c
#include <stdio.h>

class box
{
    public:
        int width, height, depth;
    box() { };
    box(int width, int height, int depth)
    {
        this->width=width;
        this->height=height;
        this->depth=depth;
    }
    void dump()
    {
        printf("this is a box. width=%d, height=%d, depth=%d\n", width, height, depth);
    }
    int get_volume()
    {
        return width * height * depth;
    }
};
class solid_object
{
    public:
        int density;
    solid_object() { };
    solid_object(int density)
    {
        this->density=density;
    }
    int get_density()
    {
        return density;
    }
    void dump()
    {
        printf("this is a solid_object. density=%d\n", density);
    }
};
class solid_box: box, solid_object
{
    public:
        solid_box (int width, int height, int depth, int density)
        {
            this->width=width;
            this->height=height;
            this->depth=depth;
            this->density=density;
        }
```
void dump()
{
    printf("this is a solid_box. width=%d, height=%d, depth=%d, density=%d\n", width, height, depth, density);
    int get_weight() { return get_volume() * get_density(); }
};

int main()
{
    box b(10, 20, 30);
solid_object so(100);
solid_box sb(10, 20, 30, 3);
b.dump();
so.dump();
sb.dump();
printf("%d\n", sb.get_weight());
return 0;
};

Let's compile it in MSVC 2008 with the /Ox and /Ob0 options and see the code of box::dump(),
solid_object::dump() and solid_box::dump():

Listing 3.93: Optimizing MSVC 2008 /Ob0

Listing 3.94: Optimizing MSVC 2008 /Ob0

Listing 3.95: Optimizing MSVC 2008 /Ob0

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
So, the memory layout for all three classes is:

**box class:**

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>width</td>
</tr>
<tr>
<td>+0x4</td>
<td>height</td>
</tr>
<tr>
<td>+0x8</td>
<td>depth</td>
</tr>
</tbody>
</table>

**solid_object class:**

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>density</td>
</tr>
</tbody>
</table>

It can be said that the **solid_box** class memory layout is **united**:

**solid_box class:**

<table>
<thead>
<tr>
<th>offset</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+0x0</td>
<td>width</td>
</tr>
<tr>
<td>+0x4</td>
<td>height</td>
</tr>
<tr>
<td>+0x8</td>
<td>depth</td>
</tr>
<tr>
<td>+0xC</td>
<td>density</td>
</tr>
</tbody>
</table>

The code of the **box::get_volume()** and **solid_object::get_density()** methods is trivial:

**Listing 3.96: Optimizing MSVC 2008 /Ob0**

```assembly
get_volume@box@@QAEHXZ PROC ; box::get_volume, COMDAT
    ; _this$ = ecx
    mov eax, DWORD PTR [ecx+8]
    imul eax, DWORD PTR [ecx+4]
    imul eax, DWORD PTR [ecx]
    ret 0
get_volume@box@@QAEHXZ ENDP ; box::get_volume
```

**Listing 3.97: Optimizing MSVC 2008 /Ob0**

```assembly
get_density@solid_object@@QAEHXZ PROC ; solid_object::get_density, COMDAT
    ; _this$ = ecx
    mov eax, DWORD PTR [ecx]
    ret 0
get_density@solid_object@@QAEHXZ ENDP ; solid_object::get_density
```

But the code of the **solid_box::get_weight()** method is much more interesting:

**Listing 3.98: Optimizing MSVC 2008 /Ob0**

```assembly
get_weight@solid_box@@QAEHXZ PROC ; solid_box::get_weight, COMDAT
    ; _this$ = ecx
    push esi
    mov esi, ecx
    push edi
    lea ecx, DWORD PTR [esi+12]
    call get_density@solid_object@@QAEHXZ ; solid_object::get_density
    mov ecx, esi
    mov edi, eax
    call get_volume@box@@QAEHXZ ; box::get_volume
    imul eax, edi
    pop edi
    pop esi
    ret 0
get_weight@solid_box@@QAEHXZ ENDP ; solid_box::get_weight
```

get_weight() just calls two methods, but for get_volume() it just passes pointer to this, and for get_density() it passes a pointer to this incremented by 12 (or 0xC) bytes, and there, in the solid_box class memory layout, the fields of the solid_object class start.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Thus, the `solid_object::get_density()` method will believe like it is dealing with the usual `solid_object` class, and the `box::get_volume()` method will work with its three fields, believing this is just the usual object of class box.

Thus, we can say, an object of a class, that inherits from several other classes, is representing in memory as a **united** class, that contains all inherited fields. And each inherited method is called with a pointer to the corresponding structure’s part.

**Virtual methods**

Yet another simple example:

```c
#include <stdio.h>

class object
{
    public:
        int color;
    object() { };
    object (int color) { this->color=color; }
    virtual void dump()
    {
        printf("color=%d\n", color);
    }
};

class box : public object
{
    private:
        int width, height, depth;
    public:
        box(int color, int width, int height, int depth)
        {
            this->color=color;
            this->width=width;
            this->height=height;
            this->depth=depth;
        }
        void dump()
        {
            printf("this is a box. color=%d, width=%d, height=%d, depth=%d\n", color, width, height, depth);
        }
};

class sphere : public object
{
    private:
        int radius;
    public:
        sphere(int color, int radius)
        {
            this->color=color;
            this->radius=radius;
        }
        void dump()
        {
            printf("this is sphere. color=%d, radius=%d\n", color, radius);
        }
};

int main()
{
    box b(1, 10, 20, 30);
    sphere s(2, 40);
    object *o1=&b;
    object *o2=&s;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Class object has a virtual method dump() that is being replaced in the inheriting box and sphere classes. If we are in an environment where it is not known the type of an object, as in the main() function in example, where the virtual method dump() is called, the information about its type must be stored somewhere, to be able to call the relevant virtual method.

Let's compile it in MSVC 2008 with the /Ox and /Ob0 options and see the code of main():

```
_s$ = -32 ; size = 12
_b$ = -20 ; size = 20
_main PROC
    sub esp, 32
    push 30
    push 20
    push 10
    push 1
    lea ecx, DWORD PTR _b$[esp+48]
call ??0box@@QAE@HHHH@Z ; box::box
    push 40
    push 2
    lea ecx, DWORD PTR _s$[esp+40]
call ??0sphere@@QAE@HH@Z ; sphere::sphere
    mov eax, DWORD PTR _b$[esp+32]
    mov edx, DWORD PTR [eax]
    lea ecx, DWORD PTR _b$[esp+32]
call edx
    mov eax, DWORD PTR _s$[esp+32]
    mov edx, DWORD PTR [eax]
    lea ecx, DWORD PTR _s$[esp+32]
call edx
    xor eax, eax
    add esp, 32
    ret 0
_main ENDP
```

A pointer to the dump() function is taken somewhere from the object. Where could we store the address of the new method? Only somewhere in the constructors: there is no other place since nothing else is called in the main() function.  

Let's see the code of the constructor of the box class:

```
??_R0?AVbox@@@8 DD FLAT:??_7type_info@6B@ ; box 'RTTI Type Descriptor'
    DD 00H
    DB '.?AVbox@', 00H

??_R1A?0A@EA@box@@8 DD FLAT:??_R0?AVbox@@@8 ; box::'RTTI Base Class Descriptor at (0,-1,0,64)'
    DD 01H
    DD 00H
    DD 0fffffffH
    DD 00H
    DD 040H
    DD FLAT:??_R3box@@8

??_R2box@@8 DD FLAT:??_R1A?0A@EA@box@@8 ; box::'RTTI Base Class Array'
    DD FLAT:??_R1A?0A@EA@object@@8

??_R3box@@8 DD 00H ; box::'RTTI Class Hierarchy Descriptor'

    DD 00H
```

29 You can read more about pointers to functions in the relevant section: [1.33 on page 387](#)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Here we see a slightly different memory layout: the first field is a pointer to some table box::$vftable' (the name has been set by the MSVC compiler).

In this table we see a link to a table named box::'RTTI Complete Object Locator' and also a link to the box::dump() method.

These are called virtual methods table and RTTI. The table of virtual methods has the addresses of methods and the RTTI table contains information about types.

By the way, the RTTI tables are used while calling dynamic_cast and typeid in C++. You can also see here the class name as a plain text string.

Thus, a method of the base object class may call the virtual method object::dump(), which in turn will call a method of an inherited class, since that information is present right in the object’s structure.

Some additional CPU time is needed for doing look-ups in these tables and finding the right virtual method address, thus virtual methods are widely considered as slightly slower than common methods.

In GCC-generated code the RTTI tables are constructed slightly differently.

### 3.19.2 ostream

Let's start again with a “hello world” example, but now we are going to use ostream:

```cpp
#include <iostream>

int main()
{
    std::cout << "Hello, world!\n";
}
```

Almost any C++ textbook tells us that the $<$ operation can be defined (overloaded) for other types. That is what is done in ostream. We see that operator$<$ is called for ostream:

Listing 3.99: MSVC 2012 (reduced listing)

```
$SG37112 DB 'Hello, world!', 0aH, 00H
```

---

30Run-Time Type Information

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's modify the example:

```cpp
#include <iostream>

int main()
{
    std::cout << "Hello, " << "world!\n";
}
```

And again, from many C++ textbooks we know that the result of each `operator<<` in `iostream` is forwarded to the next one. Indeed:

```
Listing 3.100: MSVC 2012

SG37112 DB 'world!', 0AH, 00H
SG37113 DB 'Hello, ', 00H

_main PROC
    push OFFSET $SG37113 ; 'Hello,' 
    push OFFSET $cout@std@@3V?$basic_ostream@DU?$char_traits@D@std@@@1A ; std::cout 
    call ??$76U?$char_traits@D@std@@@std@@YAAAV?$basic_ostream@DU?$char_traits@D@std@@@0@AAV10@PBD@Z
    std::operator<<<std::char_traits<char>
    add esp, 8
    xor eax, eax
    ret 0
_main ENDP
```

If we would rename `operator<<` method name to `f()`, that code will looks like:

```
f(f(std::cout, "Hello, "), "world!");
```

GCC generates almost the same code as MSVC.

### 3.19.3 References

In C++, references are pointers (3.21 on page 603) as well, but they are called **safe**, because it is harder to make a mistake while dealing with them (C++11 8.3.2).

For example, reference must always be pointing to an object of the corresponding type and cannot be NULL [Marshall Cline, C++ FAQ8.6].

Even more than that, references cannot be changed, it is impossible to point them to another object (reset) [Marshall Cline, C++ FAQ8.5].

If we are going to change the example with pointers (3.21 on page 603) to use references instead ...

```cpp
void f2 (int x, int y, int &sum, int &product)
{
    sum=x+y;
    product=x*y;
}
```
...then we can see that the compiled code is just the same as in the pointers example (3.21 on page 603):

<table>
<thead>
<tr>
<th>x$ = 8</th>
<th>; size = 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>_y$ = 12</td>
<td>; size = 4</td>
</tr>
<tr>
<td>_sum$ = 16</td>
<td>; size = 4</td>
</tr>
<tr>
<td>_product$ = 20</td>
<td>; size = 4</td>
</tr>
</tbody>
</table>

Listing 3.101: Optimizing MSVC 2010

<table>
<thead>
<tr>
<th>PROC</th>
<th>; f2</th>
</tr>
</thead>
<tbody>
<tr>
<td>mov  ecx, DWORD PTR _y$[esp-4]</td>
<td></td>
</tr>
<tr>
<td>mov  eax, DWORD PTR _x$[esp-4]</td>
<td></td>
</tr>
<tr>
<td>lea  edx, DWORD PTR [eax+ecx]</td>
<td></td>
</tr>
<tr>
<td>imul eax, ecx</td>
<td></td>
</tr>
<tr>
<td>mov ecx, DWORD PTR _product$[esp-4]</td>
<td></td>
</tr>
<tr>
<td>push esi</td>
<td></td>
</tr>
<tr>
<td>mov esi, DWORD PTR _sum$[esp]</td>
<td></td>
</tr>
<tr>
<td>mov DWORD PTR [esi], edx</td>
<td></td>
</tr>
<tr>
<td>mov DWORD PTR [ecx], eax</td>
<td></td>
</tr>
<tr>
<td>pop esi</td>
<td></td>
</tr>
<tr>
<td>ret 0</td>
<td></td>
</tr>
</tbody>
</table>

Listing 3.102: example for MSVC

```
#include <string>
#include <stdio.h>
```

(The reason why C++ functions has such strange names is explained here: 3.19.1 on page 549.)
Hence, C++ references are as much efficient as usual pointers.

3.19.4 STL

N.B.: all examples here were checked only in 32-bit environment. x64 wasn’t checked.

std::string

Internals

Many string libraries [Dennis Yurichev, C/C++ programming language notes2.2] implement a structure that contains a pointer to a string buffer, a variable that always contains the current string length (which is very convenient for many functions: [Dennis Yurichev, C/C++ programming language notes2.2.1]) and a variable containing the current buffer size.

The string in the buffer is usually terminated with zero, in order to be able to pass a pointer to the buffer into the functions that take usual C ASCII strings.

It is not specified in the C++ standard how std::string has to be implemented, however, it is usually implemented as explained above.

The C++ string is not a class (as QString in Qt, for instance) but a template (basic_string), this is made in order to support various character types: at least char and wchar_t.

So, std::string is a class with char as its base type.

And std::wstring is a class with wchar_t as its base type.

MSVC

The MSVC implementation may store the buffer in place instead of using a pointer to a buffer (if the string is shorter than 16 symbols).

This implies that a short string is to occupy at least $16 + 4 + 4 = 24$ bytes in 32-bit environment or at least $16 + 8 + 8 = 32$ bytes in 64-bit one, and if the string is longer than 16 characters, we also have to add the length of the string itself.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
struct std_string
{
    union
    {
        char buf[16];
        char* ptr;
    } u;
    size_t size; // AKA 'Mysize' in MSVC
    size_t capacity; // AKA 'Myres' in MSVC
};

void dump_std_string(std::string s)
{
    struct std_string *p=(struct std_string*)&s;
    printf("[%s] size:%d capacity:%d\n", p->size>16 ? p->u.ptr : p->u.buf, p->size, p->/\n\, capacity);
}

int main()
{
    std::string s1="a short string";
    std::string s2="a string longer than 16 bytes";

    dump_std_string(s1);
    dump_std_string(s2);

    // that works without using c_str()
    printf("%s\n", &s1);
    printf("%s\n", s2);
}

Almost everything is clear from the source code.

A couple of notes:

If the string is shorter than 16 symbols, a buffer for the string is not to be allocated in the heap.
This is convenient because in practice, a lot of strings are short indeed.

Looks like that Microsoft’s developers chose 16 characters as a good balance.

One very important thing here can be seen at the end of main(): we’re not using the c_str() method, nevertheless, if we compile and run this code, both strings will appear in the console!

This is why it works.

In the first case the string is shorter than 16 characters and the buffer with the string is located in the beginning of the std::string object (it can be treated as a structure). printf() treats the pointer as a pointer to the null-terminated array of characters, hence it works.

Printing the second string (longer than 16 characters) is even more dangerous: it is a typical programmer’s mistake (or typo) to forget to write c_str().

This works because at the moment a pointer to buffer is located at the start of structure.
This may stay unnoticed for a long time, until a longer string appears there at some time, then the process will crash.

GCC

GCC’s implementation of this structure has one more variable—reference count.

One interesting fact is that in GCC a pointer an instance of std::string instance points not to the beginning of the structure, but to the buffer pointer. In /libstdc++-v3/include/bits/basic_string.h we can read that it was done for more convenient debugging:

* The reason you want _M_data pointing to the character %array and
* not the _Rep is so that the debugger can see the string
* contents. (Probably we should add a non-inline member to get
* the _Rep for the debugger to use, so users can check the actual

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
basic_string.h source code

We consider this in our example:

### Listing 3.103: example for GCC

```cpp
#include <string>
#include <stdio.h>

struct std_string
{
    size_t length;
    size_t capacity;
    size_t refcount;
};

void dump_std_string(std::string s)
{
    char *p1=*(&s);
    // GCC type checking workaround
    struct std_string *p2=(struct std_string*)(p1-sizeof(struct std_string));
    printf("[%s] size:%d capacity:%d\n", p1, p2->length, p2->capacity);
}

int main()
{
    std::string s1="a short string";
    std::string s2="a string longer than 16 bytes"
    dump_std_string(s1);
    dump_std_string(s2);
    // GCC type checking workaround:
    printf("%s\n", *(char**)&s1);
    printf("%s\n", *(char**)&s2);
}
```

A trickery has to be used to imitate the mistake we already have seen above because GCC has stronger type checking, nevertheless, printf() works here without c_str() as well.

### A more advanced example

```cpp
#include <string>
#include <stdio.h>

int main()
{
    std::string s1="Hello, ";
    std::string s2="world!\n";
    std::string s3=s1+s2;
    printf("%s\n", s3.c_str());
}
```

### Listing 3.104: MSVC 2012

```
$SG39512 DB 'Hello', 00H
$SG39514 DB 'world!', 0aH, 00H
$SG39581 DB 's', 0aH, 00H

_s2$ = -72 ; size = 24
_s3$ = -48 ; size = 24
_s1$ = -24 ; size = 24
_main PROC
    sub    esp, 72
    push   7
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
The compiler does not construct strings statically: it would not be possible anyway if the buffer needs to be located in the heap.

Instead, the ASCII strings are stored in the data segment, and later, at runtime, with the help of the
“assign” method, the s1 and s2 strings are constructed. And with the help of operator+, the s3 string is constructed.

Please note that there is no call to the c_str() method, because its code is tiny enough so the compiler inlined it right there: if the string is shorter than 16 characters, a pointer to buffer is left in EAX, otherwise the address of the string buffer located in the heap is fetched.

Next, we see calls to the 3 destructors, they are called if the string is longer than 16 characters: then the buffers in the heap have to be freed. Otherwise, since all three std::string objects are stored in the stack, they are freed automatically, when the function ends.

As a consequence, processing short strings is faster, because of less heap accesses.

GCC code is even simpler (because the GCC way, as we saw above, is to not store shorter strings right in the structure):

```
Listing 3.105: GCC 4.8.1

.LC0:
.string "Hello, "
.LC1:
.string "world!\n"
main:
    push ebp
    mov ebp, esp
    push edi
    push esi
    push ebx
    and esp, -16
    sub esp, 32
    lea ebx, [esp+28]
    lea edi, [esp+20]
    mov DWORD PTR [esp+8], ebx
    lea esi, [esp+24]
    mov DWORD PTR [esp+4], OFFSET FLAT:.LC0
    mov DWORD PTR [esp], edi
    call _ZN6s1EPKcRKSaIcE
    mov DWORD PTR [esp+8], ebx
    mov DWORD PTR [esp+4], OFFSET FLAT:.LC1
    mov DWORD PTR [esp], esi
    call _ZN6s1EPKcRKSaIcE
    mov DWORD PTR [esp+4], edi
    mov DWORD PTR [esp], ebx
    call _ZN6s1ERKSs
    mov DWORD PTR [esp+4], esi
    mov DWORD PTR [esp], ebx
    call _ZN6s6appendERKSs
    ; inlined c_str():
    mov eax, DWORD PTR [esp+28]
    mov DWORD PTR [esp], eax
    call puts
    mov eax, DWORD PTR [esp+28]
    lea ebx, [esp+19]
    mov DWORD PTR [esp+4], ebx
    sub eax, 12
    mov DWORD PTR [esp], eax
    call _ZN6s4_Repl10_M_disposeERKSaIcE
    mov eax, DWORD PTR [esp+24]
    mov DWORD PTR [esp+4], ebx
    sub eax, 12
    mov DWORD PTR [esp], eax
    call _ZN6s4_Repl10_M_disposeERKSaIcE
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
It can be seen that it's not a pointer to the object that is passed to destructors, but rather an address 12 bytes (or 3 words) before, i.e., a pointer to the real start of the structure.

**std::string as a global variable**

Experienced C++ programmers knows that global variables of **STL** types can be defined without problems.

Yes, indeed:

```cpp
#include <stdio.h>
#include <string>

std::string s = "a string";

int main()
{
    printf ("%s\n", s.c_str());
}
```

But how and where std::string constructor will be called?

In fact, this variable is to be initialized even before main() start.

Listing 3.106: MSVC 2012: here is how a global variable is constructed and also its destructor is registered

```assembler
??__Es@@YAXXZ PROC
    push 8
    push OFFSET $SG39512 ; 'a string'
    mov ecx, OFFSET ?s@@3V?$basic_string@DU?$char_traits@D@std@@V?$allocator@D@2@@std@@A ; s
    call ?assign@?$basic_string@DU?$char_traits@D@std@@V?$allocator@D@2@@std@@A@std@@QAEAAV12@PBDI@Z
    std::basic_string<char,std::char_traits<char>,std::allocator<char> >::assign
    push OFFSET ??__Fs@@YAXXZ ; 'dynamic atexit destructor for 's''
call _atexit
    pop ecx
    ret 0
??__Es@@YAXXZ ENDP
```

Listing 3.107: MSVC 2012: here a global variable is used in main()

```assembly
$SG39512 DB 'a string', 00H $SG39519 DB '%s', 0aH, 00H

_main PROC
    cmp DWORD PTR ?s@@3V?$basic_string@DU?$char_traits@D@std@@V?$allocator@D@2@@std@@A+20, 16
    mov eax, OFFSET ?s@@3V?$basic_string@DU?$char_traits@D@std@@V?$allocator@D@2@@std@@A ; s
    cmovae eax, DWORD PTR ?s@@3V?$basic_string@DU?$char_traits@D@std@@V?$allocator@D@2@@std@@A
    push eax
    push OFFSET $SG39519 ; '%s'
call _printf
    add esp, 8
    xor eax, eax
    ret 0
_main ENDP
```

---

\[^{31}(C++) Standard Template Library\]

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
In fact, a special function with all constructors of global variables is called from CRT, before main().

More than that: with the help of atexit() another function is registered, which contain calls to all destructors of such global variables.

GCC works likewise:

Listing 3.109: GCC 4.8.1

```assembly
main:
push ebp
mov ebp, esp
and esp, -16
sub esp, 16
mov eax, DWORD PTR s
mov DWORD PTR [esp], eax
call puts
xor eax, eax
leave
ret

.LC0:
.string "a string"

GLOBAL__sub_I_s:
  sub esp, 44
  lea eax, [esp+31]
  mov DWORD PTR [esp+8], eax
  mov DWORD PTR [esp+4], OFFSET FLAT:.LC0
  mov DWORD PTR [esp], OFFSET FLAT:s
  call _ZNs1EPKcRKSaIcE
  mov DWORD PTR [esp+8], OFFSET FLAT:_dso_handle
  mov DWORD PTR [esp+4], OFFSET FLAT:s
  mov DWORD PTR [esp], OFFSET FLAT:_ZNsD1Ev
  call __cxa_atexit
  add esp, 44
  ret

.LFE645:
.size GLOBAL__sub_I_s, .-GLOBAL__sub_I_s
.section .init_array,"aw"
.align 4
.long GLOBAL__sub_I_s
.globl s
.bss
.align 4
.type s, @object
.size s, 4
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
But it does not create a separate function for this, each destructor is passed to atexit(), one by one.

**std::list**

This is the well-known doubly-linked list: each element has two pointers, to the previous and next elements.

This implies that the memory footprint is enlarged by 2 *words* for each element (8 bytes in 32-bit environment or 16 bytes in 64-bit).

C++ STL just adds the “next” and “previous” pointers to the existing structure of the type that you want to unite in a list.

Let’s work out an example with a simple 2-variable structure that we want to store in a list.

Although the C++ standard does not say how to implement it, both MSVC’s and GCC’s implementations are straightforward and similar, so here is only one source code for both:

```cpp
#include <stdio.h>
#include <list>
#include <iostream>

struct a
{
    int x;
    int y;
};

struct List_node
{
    struct List_node* _Next;
    struct List_node* _Prev;
    int x;
    int y;
};

void dump_List_node (struct List_node *n)
{
    printf ("ptr=0x%p _Next=0x%p _Prev=0x%p x=%d y=%d\n",
            n, n->_Next, n->_Prev, n->x, n->y);
}

void dump_List_vals (struct List_node* n)
{
    struct List_node* current=n;
    for (; ;)
    {
        dump_List_node (current);
        current=current->_Next;
        if (current==n) // end
            break;
    }
}

void dump_List_val (unsigned int *a)
{
    #ifdef _MSC_VER
        // GCC implementation does not have "size" field
        printf ("_Myhead=0x%p, _Mysize=%d\n", a[0], a[1]);
    #endif
    dump_List_vals ((struct List_node*)a[0]);
}

int main()
```

(For statistics collecting purposes) if you’ve read this far, please click [here](link). Thanks!
{ std::list<struct a> l;

printf("* empty list:\n");
dump_List_val((unsigned int*)(void*)&l);

struct a t1;
t1.x=1;
t1.y=2;
l.push_front(t1);
t1.x=3;
t1.y=4;
l.push_front(t1);
t1.x=5;
t1.y=6;
l.push_back(t1);

printf("* 3-elements list:\n");
dump_List_val((unsigned int*)(void*)&l);

std::list<struct a>::iterator tmp;
printf("node at .begin:\n");
tmp = l.begin();
dump_List_node((struct List_node*)(void**)&tmp);
printf("node at .end:\n");
tmp = l.end();
dump_List_node((struct List_node*)(void**)&tmp);

printf("* let's count from the beginning:\n");
std::list<struct a>::iterator it = l.begin();
printf("1st element: %d %d\n", (*it).x, (*it).y);
++it;
printf("2nd element: %d %d\n", (*it).x, (*it).y);
++it;
printf("3rd element: %d %d\n", (*it).x, (*it).y);
++it;
printf("element at .end(): %d %d\n", (*it).x, (*it).y);

printf("* let's count from the end:\n");
std::list<struct a>::iterator it2 = l.end();
printf("element at .end(): %d %d\n", (*it2).x, (*it2).y);
--it2;
printf("3rd element: %d %d\n", (*it2).x, (*it2).y);
--it2;
printf("2nd element: %d %d\n", (*it2).x, (*it2).y);
--it2;
printf("1st element: %d %d\n", (*it2).x, (*it2).y);

printf("removing last element...\n");
l.pop_back();
dump_List_val((unsigned int*)(void*)&l);
}

**GCC**

Let's start with GCC.

When we run the example, we'll see a long dump, let's work with it in pieces.

* empty list:
ptr=0x0028fe90 _Next=0x0028fe90 _Prev=0x0028fe90 x=3 y=0

Here we see an empty list.

Despite the fact it is empty, it has one element with garbage (AKA dummy node) in \( x \) and \( y \). Both the “next” and “prev” pointers are pointing to the self node:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
At this moment, the `list.begin()` and `list.end()` iterators are equal to each other.

If we push 3 elements, the list internally will be:

```
* 3-elements list:
ptr=0x000349a0 _Next=0x00034988 _Prev=0x0028fe90 x=3 y=4
ptr=0x00034988 _Next=0x00034b40 _Prev=0x000349a0 x=1 y=2
ptr=0x00034b40 _Next=0x0028fe90 _Prev=0x00034988 x=5 y=6
ptr=0x0028fe90 _Next=0x000349a0 _Prev=0x00034b40 x=5 y=6
```

The last element is still at 0x0028fe90, it not to be moved until the list’s disposal.

It still contain random garbage in $x$ and $y$ (5 and 6). By coincidence, these values are the same as in the last element, but it doesn’t mean that they are meaningful.

Here is how these 3 elements are stored in memory:

```
<table>
<thead>
<tr>
<th>Variable std::list</th>
</tr>
</thead>
<tbody>
<tr>
<td>list.begin()</td>
</tr>
</tbody>
</table>
```

The `l` variable always points to the first node.

The `list.begin()` and `list.end()` iterators are not variables, but functions, which when called return pointers to the corresponding nodes.

Having a dummy element (AKA sentinel node) is a very popular practice in implementing doubly-linked lists.

Without it, a lot of operations may become slightly more complex and, hence, slower.

The iterator is in fact just a pointer to a node. `list.begin()` and `list.end()` just return pointers.

```
node at .begin:
ptr=0x000349a0 _Next=0x00034988 _Prev=0x0028fe90 x=3 y=4
node at .end:
ptr=0x0028fe90 _Next=0x000349a0 _Prev=0x00034b40 x=5 y=6
```

The fact that the last element has a pointer to the first and the first element has a pointer to the last one remind us of circular lists.
This is very helpful here: having a pointer to the first list element, i.e., that is in the \( i \) variable, it is easy to get a pointer to the last one quickly, without the necessity to traverse the whole list.

Inserting an element at the end of the list is also quick, thanks to this feature.

\texttt{operator--} and \texttt{operator++} just set the current iterator's value to the current_node->prev or current_node->next values.

The reverse iterators (.\texttt{rbegin}, .\texttt{rend}) work just as the same, but in reverse.

\texttt{operator*} just returns a pointer to the point in the node structure, where the user's structure starts, i.e., a pointer to the first element of the structure \((x)\).

The list insertion and deletion are trivial: just allocate a new node (or deallocate) and update all pointers to be valid.

That's why an iterator may become invalid after element deletion: it may still point to the node that has been already deallocated. This is also called a \textit{dangling pointer}.

And of course, the information from the freed node (to which iterator still points) cannot be used anymore.

The GCC implementation (as of 4.8.1) doesn't store the current size of the list: this implies a slow \texttt{.size()} method: it has to traverse the whole list to count the elements, because it doesn't have any other way to get the information.

This means that this operation is \( O(n) \), i.e., it steadily gets slower as the list grows.

\begin{verbatim}
main proc near
    push ebp
    mov ebp, esp
    push esi
    push ebx
    and esp, 0FFFFFFF0h
    sub esp, 20h
    lea ebx, [esp+10h]
    mov dword ptr [esp], offset s ; "empty list:"
    mov [esp+10h], ebx
    mov [esp+14h], ebx
    call puts
    mov [esp], ebx
    call _Z13dump_List_valPj ; dump_List_val(uint *)
    lea esi, [esp+18h]
    mov [esp+4], esi
    mov [esp], ebx

MSVC

MSVC’s implementation (2012) is just the same, but it also stores the current size of the list.  
This implies that the .size() method is very fast ($O(1)$): it just reads one value from memory.  
On the other hand, the size variable must be updated at each insertion/deletion.  
MSVC’s implementation is also slightly different in the way it arranges the nodes:
GCC has its dummy element at the end of the list, while MSVC’s is at the beginning.

Listing 3.112: Optimizing MSVC 2012 /Fa2.asm /GS- /Ob1

Unlike GCC, MSVC’s code allocates the dummy element at the start of the function with the help of the “Buynode” function, it is also used to allocate the rest of the nodes (GCC’s code allocates the first element in the local stack).

Listing 3.113: The whole output

**C++11 std::forward_list**

The same thing as std::list, but singly-linked one, i.e., having only the “next” field at each node. It has a smaller memory footprint, but also don’t offer the ability to traverse list backwards.

**std::vector**

We would call std::vector a safe wrapper of the **PODT** array. Internally it is somewhat similar to std::string (3.19.4 on page 566): it has a pointer to the allocated buffer, a pointer to the end of the array, and a pointer to the end of the allocated buffer.

The array’s elements lie in memory adjacently to each other, just like in a normal array (1.26 on page 268). In C++11 there is a new method called .data(), that returns a pointer to the buffer, like .c_str() in std::string.

The buffer allocated in the heap can be larger than the array itself.

Both MSVC’s and GCC’s implementations are similar, just the names of the structure’s fields are slightly different, so here is one source code that works for both compilers. Here is again the C-like code for dumping the structure of std::vector:

```c
#include <stdio.h>
#include <vector>
#include <algorithm>
#include <functional>

struct vector_of_ints
{
    // MSVC names:
    int *Myfirst;
    int *Mylast;
    int *Myend;

    // GCC structure is the same, but names are: _M_start, _M_finish, _M_end_of_storage
};

void dump(struct vector_of_ints *in)
{
    //...
}
```

---

32(C++) Plain Old Data Type

As it can be seen, there is no allocated buffer when main() starts. After the first push_back() call, a buffer is allocated. And then, after each push_back() call, both array size and buffer size (capacity) are increased. But the buffer address changes as well, because push_back() reallocates the buffer in the heap each time. It is costly operation, that’s why it is very important to predict the size of the array in the future and reserve enough space for it with the .reserve() method.

The last number is garbage: there are no array elements at this point, so a random number is printed. This illustrates the fact that operator[] of std::vector does not check of the index is in the array’s bounds. The slower .at() method, however, does this checking and throws an std::out_of_range exception in case of error.

Let's see the code:

Listing 3.114: MSVC 2012 /GS- /Ob1

We see how the .at() method checks the bounds and throws an exception in case of error. The number that the last printf() call prints is just taken from the memory, without any checks.

One may ask, why not use the variables like “size” and “capacity”, like it was done in std::string. Supposedly, this was done for faster bounds checking.

The code GCC generates is in general almost the same, but the .at() method is inlined:

Listing 3.115: GCC 4.8.1 -fno-inline-small-functions -O1

main endp

 réserve() is inlined as well. It calls new() if the buffer is too small for the new size, calls memmove() to copy the contents of the buffer, and calls delete() to free the old buffer.

Let's also see what the compiled program outputs if compiled with GCC:

_MYfirst=0x(nil), _MYlast=0x(nil), _MYend=0x(nil)
size=0, capacity=0
_MYfirst=0x8257008, _MYlast=0x825700c, _MYend=0x825700c
size=1, capacity=1
element 0: 1
_MYfirst=0x8257018, _MYlast=0x8257020, _MYend=0x8257020
size=2, capacity=2
element 0: 1
element 1: 2
_MYfirst=0x8257028, _MYlast=0x8257034, _MYend=0x8257038

We can spot that the buffer size grows in a different way that in MSVC.
Simple experimentation shows that in MSVC’s implementation the buffer grows by ~50% each time it needs to be enlarged, while GCC’s code enlarges it by 100% each time, i.e., doubles it.

**std::map and std::set**

The binary tree is another fundamental data structure.

As its name states, this is a tree where each node has at most 2 links to other nodes. Each node has key and/or value: std::set provides only key at each node, std::map provides both key and value at each node.

Binary trees are usually the structure used in the implementation of “dictionaries” of key-values (AKA “associative arrays”).

There are at least three important properties that a binary trees has:

- All keys are always stored in sorted form.
- Keys of any types can be stored easily. Binary tree algorithms are unaware of the key’s type, only a key comparison function is required.
- Finding a specific key is relatively fast in comparison with lists and arrays.

Here is a very simple example: let’s store these numbers in a binary tree: 0, 1, 2, 3, 5, 6, 9, 10, 11, 12, 20, 99, 100, 101, 107, 1001, 1010.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
All keys that are smaller than the node key’s value are stored on the left side.

All keys that are bigger than the node key’s value are stored on the right side.

Hence, the lookup algorithm is straightforward: if the value that you are looking for is smaller than the current node’s key value: move left, if it is bigger: move right, stop if the value required is equal to the node key’s value.

That is why the searching algorithm may search for numbers, text strings, etc., as long as a key comparison function is provided.

All keys have unique values.

Having that, one needs \( \approx \log_2 n \) steps in order to find a key in a balanced binary tree with \( n \) keys. This implies that \( \approx 10 \) steps are needed \( \approx 1000 \) keys, or \( \approx 13 \) steps for \( \approx 10000 \) keys.

Not bad, but the tree has always to be balanced for this: i.e., the keys has to be distributed evenly on all levels. The insertion and removal operations do some maintenance to keep the tree in a balanced state.

There are several popular balancing algorithms available, including the AVL tree and the red-black tree. The latter extends each node with a “color” value to simplify the balancing process, hence, each node may be “red” or “black”.

Both GCC’s and MSVC’s \texttt{std::map} and \texttt{std::set} template implementations use red-black trees. \texttt{std::set} has only keys. \texttt{std::map} is the “extended” version of \texttt{std::set}: it also has a value at each node.

\textbf{MSVC}

```cpp
#include <map>
#include <set>
#include <string>
#include <iostream>

// Structure is not packed! Each field occupies 4 bytes.
struct tree_node
{
    struct tree_node *Left;
    struct tree_node *Parent;
    struct tree_node *Right;
    char Color; // 0 - Red, 1 - Black
    char Isnil;
    //std::pair Myval;
    unsigned int first; // called Myval in std::set
    const char *second; // not present in std::set
};

struct tree_struct
{
    struct tree_node *Myhead;
    size_t Mysize;
};
```

The structure is not packed, so both char values occupy 4 bytes each.

As for std::map, first and second can be viewed as a single value of type std::pair. std::set has only one value at this address in the structure instead.

The current size of the tree is always present, as in the case of the implementation of std::list in MSVC (3.19.4 on page 578).

As in the case of std::list, the iterators are just pointers to nodes. The .begin() iterator points to the minimal key.

That pointer is not stored anywhere (as in lists), the minimal key of the tree is looked up every time.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
operator-- and operator++ move the current node pointer to the predecessor or successor respectively, i.e., the nodes which have the previous or next key.

The algorithms for all these operations are explained in [Cormen, Thomas H. and Leiserson, Charles E. and Rivest, Ronald L. and Stein, Clifford, *Introduction to Algorithms, Third Edition*, (2009)].

The .end() iterator points to the dummy node, it has 1 in Isnil, which implies that the node has no key and/or value. It can be viewed as a “landing zone” in HDD\(^{34}\) and often called *sentinel* [see N. Wirth, *Algorithms and Data Structures*, 1985]\(^{35}\).

The “parent” field of the dummy node points to the root node, which serves as a vertex of the tree and contains information.

**GCC**

```c
#include <stdio.h>
#include <map>
#include <set>
#include <string>
#include <iostream>

struct map_pair
{
    int key;
    const char *value;
};

s.end():
ptr=0x0028FE24 M_left=0x01D5D870 M_parent=0x007A4BE0 M_right=0x01D5D8D0 M_color=0

GCC’s implementation is very similar \(^{36}\). The only difference is the absence of the Isnil field, so the structure occupies slightly less space in memory than its implementation in MSVC.

The dummy node is also used as a place to point the .end() iterator also has no key and/or value.

### Rebalancing demo (GCC)

Here is also a demo showing us how a tree is rebalanced after some insertions.

```
Listing 3.118: GCC

#include <stdio.h>
#include <map>
#include <set>
#include <string>
#include <iostream>

struct map_pair
{
    int key;
    const char *value;
};

struct tree_node
{
int M_color; // 0 - Red, 1 - Black
struct tree_node *M_parent;
struct tree_node *M_left;
struct tree_node *M_right;
};

struct tree_struct
{
    int M_key_compare;
    struct tree_node M_header;
    size_t M_node_count;
};

const char* ALOT_OF_TABS="						"

void dump_as_tree (int tabs, struct tree_node *n)
{
    void *point_after_struct=((char*)n)+sizeof(struct tree_node);
    printf( "%d\n", *(int*)point_after_struct);
    if (n->M_left)
    {
        printf("%.*sL-------", tabs, ALOT_OF_TABS);
        dump_as_tree (tabs+1, n->M_left);
    }
    if (n->M_right)
    {
        printf("%.*sR-------", tabs, ALOT_OF_TABS);
        dump_as_tree (tabs+1, n->M_right);
    }
};

void dump_map_and_set(struct tree_struct *m)
{
    printf("root----");
    dump_as_tree (1, m->M_header.M_parent);
};

int main()
{
    std::set<int> s;
    s.insert(123);
s.insert(456);
    printf("123, 456 has been inserted\n");
    dump_map_and_set (((struct tree_struct *) (void*))&s);
    s.insert(11);
    s.insert(12);
    printf("\n");
    printf("11, 12 has been inserted\n");
    dump_map_and_set (((struct tree_struct *) (void*))&s);
    s.insert(100);
    s.insert(1001);
    printf("\n");
    printf("100, 1001 has been inserted\n");
    dump_map_and_set (((struct tree_struct *) (void*))&s);
    s.insert(667);
    s.insert(1);
    s.insert(4);
    s.insert(7);
    printf("\n");
    printf("667, 1, 4, 7 has been inserted\n");
    dump_map_and_set (((struct tree_struct *) (void*))&s);
    printf("\n");
};

Listing 3.119: GCC 4.8.1

123, 456 has been inserted
root----123

3.19.5 Memory

Sometimes you may hear from C++ programmers “allocate memory on stack” and/or “allocate memory on heap”.

Allocating object on stack:

```cpp
void f()
{
    ...
    Class o=Class(...);
    ...
}
```

The memory for object (or structure) is allocated in stack, using simple SP shift. The memory is deallocated upon function exit, or, more precisely, at the end of scope—SP is returning to its state (same as at the start of function) and destructor of Class is called. In the same manner, memory for allocated structure in C is deallocated upon function exit.

Allocating object on heap:

```cpp
void f1()
{
    ...
    Class *o=new Class(...);
    ...
}
void f2()
{
    ...
    delete o;
    ...
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This is the same as allocating memory for a structure using `malloc()` call. In fact, `new` in C++ is wrapper for `malloc()`, and `delete` is wrapper for `free()`. Since memory block has been allocated in heap, it must be deallocated explicitly, using `delete`. Class destructor will be automatically called right before that moment.

Which method is better? Allocating on stack is very fast, and good for small, short-lived object, which will be used only in the current function.

Allocating on heap is slower, and better for long-lived object, which will be used across many functions. Also, objects allocated in heap are prone to memory leakage, because they must to be freed explicitly, but one can forget about it.

Anyway, this is matter of taste.

### 3.20 Negative array indices

It’s possible to address the space before an array by supplying a negative index, e.g., `array[-1].`

#### 3.20.1 Addressing string from the end

Python PL allows to address arrays and strings from the end. For example, `string[-1]` returns the last character, `string[-2]` returns penultimate, etc. Hard to believe, but this is also possible in C/C++:

```c
#include <string.h>
#include <stdio.h>

int main()
{
    char *s="Hello, world!";
    char *s_end=s+strlen(s);
    printf ("last character: %c\n", s_end[-1]);
    printf ("penultimate character: %c\n", s_end[-2]);
}
```

It works, but `s_end` must always has an address of terminating zero byte at the end of `s` string. If `s` string’s size get changed, `s_end` must be updated.

The trick is dubious, but again, this is a demonstration of negative indices.

#### 3.20.2 Addressing some kind of block from the end

Let’s first recall why stack grows backwards (1.9.1 on page 30). There is some kind of block in memory and you want to store both heap and stack there, and you are not sure, how big they both can grow during runtime.

You can set a heap pointer to the beginning of the block, then you can set a stack pointer to the end of the block (heap + size_of_block), and then you can address nth element of stack like `stack[-n]`. For example, `stack[-1]` for 1st element, `stack[-2]` for 2nd, etc.

This will work in the same fashion, as our trick of addressing string from the end.

You can easily check if the structures has not begun to overlap each other: just be sure that address of the last element in heap is below the address of the last element of stack.

Unfortunately, -0 as index will not work, since two’s complement way of representing negative numbers (2.2 on page 458) don’t allow negative zero, so it cannot be distinguished from positive zero.

This method is also mentioned in “Transaction processing”, Jim Gray, 1993, “The Tuple-Oriented File System” chapter, p. 755.
3.20.3 Arrays started at 1

Fortran and Mathematica defined first element of array as 1th, probably because this is tradition in mathematics. Other PLs like C/C++ defined it as 0th. Which is better? Edsger W. Dijkstra argued that latter is better.

But programmers may still have a habit after Fortran, so using this little trick, it’s possible to address the first element in C/C++ using index 1:

```c
#include <stdio.h>

int main()
{
    int random_value=0x11223344;
    unsigned char array[10];
    int i;
    unsigned char *fakearray=&array[-1];

    for (i=0; i<10; i++)
        array[i]=i;

    printf ("first element %d\n", fakearray[1]);
    printf ("second element %d\n", fakearray[2]);
    printf ("last element %d\n", fakearray[10]);

    printf ("array[-1]=%02X, array[-2]=%02X, array[-3]=%02X, array[-4]=%02X\n", 
            array[-1],
            array[-2],
            array[-3],
            array[-4]);
}
```

Listing 3.120: Non-optimizing MSVC 2010

---

37See https://www.cs.utexas.edu/users/EWD/transcriptions/EWD08xx/EWD831.html

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
mov ecx, DWORD PTR _fakearray$[ebp]
; ecx=address of fakearray[1] or array[0]
movzx edx, BYTE PTR [ecx+1]
push edx
push OFFSET $SG2751 ; 'first element %d'
call _printf
add esp, 8
mov eax, DWORD PTR _fakearray$[ebp]
; eax=address of fakearray[0], eax+1 is fakearray[1] or array[0]
movzx edx, BYTE PTR [eax+1]
push edx
push OFFSET $SG2752 ; 'second element %d'
call _printf
add esp, 8
mov edx, DWORD PTR _fakearray$[ebp]
; edx=address of fakearray[0], edx+10 is fakearray[10] or array[9]
movzx eax, BYTE PTR [edx+10]
push eax
push OFFSET $SG2753 ; 'last element %d'
call _printf
add esp, 8

lea ecx, DWORD PTR _array$[ebp]
movzx edx, BYTE PTR [ecx-4]
push edx
lea eax, DWORD PTR _array$[ebp]
movzx ecx, BYTE PTR [eax-3]
push ecx
lea edx, DWORD PTR _array$[ebp]
movzx eax, BYTE PTR [edx-2]
push eax
lea edx, DWORD PTR _array$[ebp]
movzx eax, BYTE PTR [ecx-1]
push edx
push OFFSET $SG2754 ;
array[-1]=%02X, array[-2]=%02X, array[-3]=%02X, array[-4]=%02X'
call _printf
add esp, 20
xor eax, eax
mov esp, ebp
pop ebp
ret 0
_main ENDP

So we have array[] of ten elements, filled with 0...9 bytes.
Then we have the fakearray[] pointer, which points one byte before array[].
fakearray[1] points exactly to array[0]. But we are still curious, what is there before array[]? We have added random_value before array[] and set it to 0x11223344. The non-optimizing compiler allocated the variables in the order they were declared, so yes, the 32-bit random_value is right before the array.

We ran it, and:

first element 0
second element 1
last element 9

Here is the stack fragment we will copy/paste from OllyDbg’s stack window (with comments added by the author):

<table>
<thead>
<tr>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>001DFBCCC</td>
<td>/001DFBD3 ; fakearray pointer</td>
</tr>
<tr>
<td>001DFBD0</td>
<td>11223344 ; random_value</td>
</tr>
<tr>
<td>001DFBD4</td>
<td>03020100 ; 4 bytes of array[]</td>
</tr>
<tr>
<td>001DFBD8</td>
<td>07060504 ; 4 bytes of array[]</td>
</tr>
<tr>
<td>001DFBDC</td>
<td>00CB0908 ; random garbage + 2 last bytes of array[]</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The pointer to the fakearray[] (0x001DFBD3) is indeed the address of array[] in the stack (0x001DFBD4), but minus 1 byte.

It's still very hackish and dubious trick. Doubtfully anyone should use it in production code, but as a demonstration, it fits perfectly here.

### 3.21 More about pointers

The way C handles pointers, for example, was a brilliant innovation; it solved a lot of problems that we had before in data structuring and made the programs look good afterwards.

---

Donald Knuth, interview (1993)

For those, who still have hard time understanding C/C++ pointers, here are more examples. Some of them are weird and serves only demonstration purpose: use them in production code only if you really know what you’re doing.

#### 3.21.1 Working with addresses instead of pointers

Pointer is just an address in memory. But why we write char* string instead of something like address string? Pointer variable is supplied with a type of the value to which pointer points. So then compiler will be able to catch data typization bugs during compilation.

To be pedantic, data typing in programming languages is all about preventing bugs and self-documentation. It’s possible to use maybe two of data types like int (or int64_t) and byte—these are the only types which are available to assembly language programmers. But it’s just very hard task to write big and practical assembly programs without nasty bugs. Any small typo can lead to hard-to-find bug.

Data type information is absent in a compiled code (and this is one of the main problems for decompilers), and I can demonstrate this.

This is what sane C/C++ programmer can write:

```c
#include <stdio.h>
#include <stdint.h>

void print_string (char *s)
{
    printf ("(address: 0x%llx)\n", s);
    printf ("%s\n", s);
}

int main()
{
    char *s="Hello, world!";
    print_string (s);
}
```

This is what I can write:

```c
#include <stdio.h>
#include <stdint.h>

void print_string (uint64_t address)
{
    printf ("(address: 0x%llx)\n", address);
    puts ((char*)address);
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
int main()
{
    char *s="Hello, world!";
    print_string ((uint64_t)s);
}
```

I use `uint64_t` because I run this example on Linux x64. `int` would work for 32-bit OS-es. First, a pointer to character (the very first in the greeting string) is casted to `uint64_t`, then it's passed further. `print_string()` function casts back incoming `uint64_t` value into pointer to a character.

What is interesting is that GCC 4.8.4 produces identical assembly output for both versions:

```
gcc 1.c -S -masm=intel -O3 -fno-inline

.LC0:
    .string "(address: 0x%llx)\n"
print_string:
    push    rbx
    mov     rdx, rdi
    mov     rbx, rdi
    mov     esi, OFFSET FLAT:.LC0
    mov     edi, 1
    xor     eax, eax
    call    __printf_chk
    mov     rdi, rbx
    pop      rbx
    jmp      puts
.LC1:
    .string "Hello, world!"
main:
    sub      rsp, 8
    mov      edi, OFFSET FLAT:.LC1
    call     print_string
    add      rsp, 8
    ret
```

(I've removed all insignificant GCC directives.)

I also tried UNIX `diff` utility and it shows no differences at all.

Let's continue to abuse C/C++ programming traditions heavily. Someone may write this:

```c
#include <stdio.h>
#include <stdint.h>

uint8_t load_byte_at_address (uint8_t* address)
{
    return *address;
    //this is also possible: return address[0];
};

void print_string (char *s)
{
    char* current_address=s;
    while (1)
    {
        char current_char=load_byte_at_address(current_address);
        if (current_char==0)
            break;
        printf ("%c", current_char);
        current_address++;
    }
};

int main()
{
    char *s="Hello, world!";
}
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
It can be rewritten like this:

```c
#include <stdio.h>
#include <stdint.h>

uint8_t load_byte_at_address (uint64_t address)
{
    return *(uint8_t*)address;
};

void print_string (uint64_t address)
{
    uint64_t current_address=address;
    while (1)
    {
        char current_char=load_byte_at_address(current_address);
        if (current_char==0)
            break;
        printf ("%c", current_char);
        current_address++;
    }
};

int main()
{
    char *s="Hello, world!";
    print_string ((uint64_t)s);
};
```

Both source codes resulting in the same assembly output:

```
gcc 1.c -S -masm=intel -O3 -fno-inline
```

(I have also removed all insignificant GCC directives.)

No difference: C/C++ pointers are essentially addresses, but supplied with type information, in order to prevent possible mistakes at the time of compilation. Types are not checked during runtime—it would be huge (and unneeded) overhead.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
606

3.21.2 Passing values as pointers; tagged unions
Here is an example on how to pass values in pointers:
#include <stdio.h>
#include <stdint.h>
uint64_t multiply1 (uint64_t a, uint64_t b)
{
return a*b;
};
uint64_t* multiply2 (uint64_t *a, uint64_t *b)
{
return (uint64_t*)((uint64_t)a*(uint64_t)b);
};
int main()
{
printf ("%d\n", multiply1(123, 456));
printf ("%d\n", (uint64_t)multiply2((uint64_t*)123, (uint64_t*)456));
};

It works smoothly and GCC 4.8.4 compiles both multiply1() and multiply2() functions identically!
multiply1:
mov
imul
ret

rax, rdi
rax, rsi

multiply2:
mov
imul
ret

rax, rdi
rax, rsi

As long as you do not dereference pointer (in other words, you don’t read any data from the address stored
in pointer), everything will work ﬁne. Pointer is a variable which can store anything, like usual variable.
Signed multiplication instruction (IMUL) is used here instead of unsigned one (MUL), read more about it
here: 2.2.1 on page 459.
By the way, it’s well-known hack to abuse pointers a little called tagged pointers. In short, if all your
pointers points to blocks of memory with size of, let’s say, 16 bytes (or it is always aligned on 16-byte
boundary), 4 lowest bits of pointer is always zero bits and this space can be used somehow. It’s very
popular in LISP compilers and interpreters. They store cell/object type in these unused bits, this can save
some memory. Even more, you can judge about cell/object type using just pointer, with no additional
memory access. Read more about it: [Dennis Yurichev, C/C++ programming language notes1.3].

3.21.3 Pointers abuse in Windows kernel
The resource section of PE executable ﬁle in Windows OS is a section containing pictures, icons, strings,
etc. Early Windows versions allowed to address resources only by IDs, but then Microsoft added a way to
address them using strings.
So then it would be possible to pass ID or string to FindResource() function. Which is declared like this:
HRSRC WINAPI FindResource(
_In_opt_ HMODULE hModule,
_In_
LPCTSTR lpName,
_In_
LPCTSTR lpType
);

lpName and lpType has char* or wchar* types, and when someone still wants to pass ID, he/she have to
use MAKEINTRESOURCE macro, like this:
result = FindResource(..., MAKEINTRESOURCE(1234), ...);

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!


It’s interesting fact that MAKEINTRESOURCE is merely casting integer to pointer. In MSVC 2013, in the file `MicrosoftSDKs\Windows\v7.1A\Include\Ks.h` we can find this:

```
#if (!defined( MAKEINTRESOURCE ))
define MAKEINTRESOURCE( res ) ((ULONG_PTR) (USHORT) res)
#endif
```

Sounds insane. Let’s peek into ancient leaked Windows NT4 source code. In `private/windows/base/client/module.c` we can find `FindResource()` source code:

```
HRSRC
FindResourceA(
    HMODULE hModule,
    LPCSTR lpName,
    LPCSTR lpType
)
{
    NTSTATUS Status;
    ULONG IdPath[ 3 ];
    PVOID p;
    IdPath[ 0 ] = 0;
    IdPath[ 1 ] = 0;
    try {
        if ((IdPath[ 0 ] = BaseDllMapResourceIdA( lpType )) == -1) {
            Status = STATUS_INVALID_PARAMETER;
        } else
        if ((IdPath[ 1 ] = BaseDllMapResourceIdA( lpName   )) == -1) {
            Status = STATUS_INVALID_PARAMETER;
        }
    }

Let's proceed to `BaseDllMapResourceIdA()` in the same source file:

```
ULONG
BaseDllMapResourceIdA(
    LPCSTR lpId
)
{
    NTSTATUS Status;
    ULONG Id;
    UNICODE_STRING UnicodeString;
    ANSI_STRING AnsiString;
    PWSTR s;
    try {
        if ((ULONG)lpId & LDR_RESOURCE_ID_NAME_MASK) {
            if (*lpId == '#') {
                Status = RtlCharToInteger( lpId+1, 10, &Id );
                if (!NT_SUCCESS( Status ) || Id & LDR_RESOURCE_ID_NAME_MASK) {
                    if (NT_SUCCESS( Status )) {
                        Status = STATUS_INVALID_PARAMETER;
                    } else {
                        RtlInitAnsiString( &AnsiString, lpId );
                        Status = RtlAnsiStringToUnicodeString( &UnicodeString,
                                                                  &AnsiString,
                                                                  TRUE );
                    }
                } else {
                    BaseSetLastNTError( Status );
                    Id = (ULONG)-1;
                }
            }
        } else {
            RtlInitAnsiString( &AnsiString, lpId );
            Status = RtlAnsiStringToUnicodeString( &UnicodeString,
                                                  &AnsiString,
                                                  TRUE );
        }
    }
```
if (!NT_SUCCESS(Status)) {
    BaseSetLastNtError(Status);
    Id = (ULONG)-1;
} else {
    s = UnicodeString.Buffer;
    while (*s != UNICODE_NULL) {
        *s = RtlUpcaseUnicodeChar(*s);
        s++;
    }
    Id = (ULONG)UnicodeString.Buffer;
} else {
    Id = (ULONG)lpId;
}

except(EXCEPTION_EXECUTE_HANDLER) {
    BaseSetLastNtError(GetExceptionCode());
    Id = (ULONG)-1;
}
return Id;

lpId is ANDed with LDR_RESOURCE_ID_NAME_MASK.
Which we can find in public/sdk/inc/ntldr.h:

... #define LDR_RESOURCE_ID_NAME_MASK 0xFFFF0000 ...

So lpId is ANDed with 0xFFFF0000 and if some bits beyond lowest 16 bits are still present, first half of function is executed (lpId is treated as an address of string). Otherwise—second half (lpId is treated as 16-bit value).

Still, this code can be found in Windows 7 kernel32.dll file:

....

If value in input pointer is greater than 0x10000, jump to string processing is occurred. Otherwise, input value of lpId is returned as is. 0xFFFF0000 mask is not used here any more, because this is 64-bit code after all, but still, 0xFFFFFFFFFFFF0000 could work here.

Attentive reader may ask, what if address of input string is lower than 0x10000? This code relied on the fact that in Windows there are nothing on addresses below 0x10000, at least in Win32 realm.

Raymond Chen writes about this:

How does MAKEINTRESOURCE work? It just stashes the integer in the bottom 16 bits of a pointer, leaving the upper bits zero. This relies on the convention that the first 64KB of address space is never mapped to valid memory, a convention that is enforced starting in Windows 7.

In short words, this is dirty hack and probably one should use it only if there is a real necessity. Perhaps, FindResource() function in past had SHORT type for its arguments, and then Microsoft has added a way to pass strings there, but older code must also be supported.

Now here is my short distilled example:

```c
#include <stdio.h>
#include <stdint.h>

void f(char* a)
{
    if (((uint64_t)a)>0x10000)
        printf ("Pointer to string has been passed: %s\n", a);
    else
        printf ("16-bit value has been passed: %d\n", (uint64_t)a);
};

int main()
{
    f("Hello!"); // pass string
    f((char*)1234); // pass 16-bit value
};
```

It works!

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Pointers abuse in Linux kernel

As it has been noted in comments on Hacker News, Linux kernel also has something like that.

For example, this function can return both error code and pointer:

```c
struct kernfs_node *kernfs_create_link(struct kernfs_node *parent,
const char *name,
struct kernfs_node *target)
{
    struct kernfs_node *kn;
    int error;
    kn = kernfs_new_node(parent, name, S_IFLNK|S_IRWXUGO, KERNFS_LINK);
    if (!kn)
        return ERR_PTR(-ENOMEM);
    if (kernfs_ns_enabled(parent))
        kn->ns = target->ns;
    kn->symlink.target_kn = target;
    kernfs_get(target); /* ref owned by symlink */
    error = kernfs_add_one(kn);
    if (!error)
        return kn;
    kernfs_put(kn);
    return ERR_PTR(error);
}
```

([https://github.com/torvalds/linux/blob/fceef393a538134f03b778c5d2519e670269342f/fs/kernfs/symlink.c#L25](https://github.com/torvalds/linux/blob/fceef393a538134f03b778c5d2519e670269342f/fs/kernfs/symlink.c#L25))

`ERR_PTR` is a macro to cast integer to pointer:

```c
static inline void *__must_check ERR_PTR(long error)
{
    return (void *) error;
}
```

([https://github.com/torvalds/linux/blob/61d0b5a4b2777dcf5daef245e212b3c1fa8091ca/tools/virtio/linux/err.h](https://github.com/torvalds/linux/blob/61d0b5a4b2777dcf5daef245e212b3c1fa8091ca/tools/virtio/linux/err.h))

This header file also has a macro helper to distinguish error code from pointer:

```c
#define IS_ERR_VALUE(x) unlikely((x) >= (unsigned long)-MAX_ERRNO)
```

This means, error codes are the “pointers” which are very close to -1 and, hopefully, there are nothing in kernel memory on the addresses like 0xFFFFFFFFFFFFFFFF, 0xFFFFFFFFFFFFFFFE, 0xFFFFFFFFFFFFFFFFFD, etc.

Much more popular solution is to return NULL in case of error and to pass error code via additional argument. Linux kernel authors don’t do that, but everyone who use these functions must always keep in mind that returning pointer must always be checked with `IS_ERR_VALUE` before dereferencing.

For example:

```c
fman->cam_offset = fman_muram_alloc(fman->muram, fman->cam_size);
if (IS_ERR_VALUE(fman->cam_offset)) {
    dev_err(fman->dev, "%s: MURAM alloc for DMA CAM failed
", __func__);
    return -ENOMEM;
}
```

([https://github.com/torvalds/linux/blob/aa00edc1287a693eadc7bc67a3d73555d969b35d/drivers/net/ethernet/freescale/fman/fman.c#L826](https://github.com/torvalds/linux/blob/aa00edc1287a693eadc7bc67a3d73555d969b35d/drivers/net/ethernet/freescale/fman/fman.c#L826))
Pointers abuse in UNIX userland

mmap() function returns -1 in case of error (or MAP_FAILED, which equals to -1). Some people say, mmap() can map a memory at zeroth address in rare situations, so it can’t use 0 or NULL as error code.

3.21.4 Null pointers

“Null pointer assignment” error of MS-DOS era

Oldschool readers may recall a weird error message of MS-DOS era: “Null pointer assignment”. What does it mean?

It’s not possible to write a memory at zero address in *NIX and Windows OSes, but it was possible to do so in MS-DOS due to absence of memory protection whatsoever.

So I’ve pulled my ancient Turbo C++ 3.0 (later it was renamed to Borland C++) from early 1990s and tried to compile this:

```
#include <stdio.h>

int main()
{
    int *ptr=NULL;
    *ptr=1234;
    printf("Now let's read at NULL\n");
    printf("%d\n", *ptr);
}
```

Hard to believe, but it works, with error upon exit, though:

```
C:\TC30\BIN\1
Now let's read at NULL
1234
Null pointer assignment
C:\TC30\BIN>
```

Let’s dig deeper into the source code of CRT of Borland C++ 3.1, file c0.asm:

```
; __checknull() check for null pointer zapping copyright message

...;

; Check for null pointers before exit

__checknull PROC DIST
    PUBLIC __checknull

IF  LDATA EQ false
    IFNDEF __TINY_
        push si
        push di
        mov es, cs:DGROUP@@
        xor ax, ax
        mov si, ax
        mov cx, lgth_CopyRight
        ComputeChecksum label near
        add al, es:[si]
        adc ah, 0
        inc si
        loop ComputeChecksum
        sub ax, CheckSum
        jz @0SumOK
        mov cx, lgth_NullCheck
        mov dx, offset DGROUP: NullCheck
        call ErrorDisplay

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```
The MS-DOS memory model was really weird (11.6 on page 976) and probably not worth looking into it unless you're fan of retrocomputing or retrogaming. One thing we have to keep in mind is that memory segment (included data segment) in MS-DOS is a memory segment in which code or data is stored, but unlike "serious" OSes, it's started at address 0.

And in Borland C++ CRT, the data segment is started with 4 zero bytes and the copyright string “Borland C++ - Copyright 1991 Borland Intl.”. The integrity of the 4 zero bytes and text string is checked upon exit, and if it's corrupted, the error message is displayed.

But why? Writing at null pointer is common mistake in C/C++, and if you do so in *NIX or Windows, your application will crash. MS-DOS has no memory protection, so CRT has to check this post-factum and warn about it upon exit. If you see this message, this means, your program at some point has written at address 0.

Our program did so. And this is why 1234 number has been read correctly: because it was written at the place of the first 4 zero bytes. Checksum is incorrect upon exit (because the number has been left there), so error message has been displayed.

Am I right? I've rewritten the program to check my assumptions:

```c
#include <stdio.h>

int main()
{
    int *ptr=NULL;
    *ptr=1234;
    printf ("Now let's read at NULL\n");
    printf ("%d\n", *ptr);
    *ptr=0; // psst, cover our tracks!
}
```

This program executes without error message upon exit.

Though method to warn about null pointer assignment is relevant for MS-DOS, perhaps, it can still be used today in low-cost MCUs with no memory protection and/or MMU.

---

38Memory Management Unit
Why would anyone write at address 0?

But why would a sane programmer write a code which writes something at address 0? It can be done accidentally: for example, a pointer must be initialized to newly allocated memory block and then passed to some function which returns data through pointer.

```c
int *ptr=NULL;
...
we forgot to allocate memory and initialize ptr
strcpy (ptr, buf);  // strcpy() terminates silently because MS-DOS has no memory protection
```

Even worse:

```c
int *ptr=malloc(1000);
...
we forgot to check if memory has been really allocated: this is MS-DOS after all and \ computers had small amount of RAM,
... and RAM shortage was very common.
... if malloc() returned NULL, the ptr will also be NULL.
strcpy (ptr, buf);  // strcpy() terminates silently because MS-DOS has no memory protection
```

Writing on 0th address on purpose

Here is an example from dmalloc\(^{39}\), a portable way of generating core dump, if other ways are not available:

3.4 Generating a Core File on Errors
====================================

If the 'error-abort' debug token has been enabled, when the library detects any problems with the heap memory, it will immediately attempt to dump a core file. *Note Debug Tokens:. Core files are a complete copy of the program and its state and can be used by a debugger to see specifically what is going on when the error occurred. *Note Using With a Debugger:. By default, the low, medium, and high arguments to the library utility enable the 'error-abort' token. You can disable this feature by entering 'dmalloc -m error-abort' (-m for minus) to remove the 'error-abort' token and your program will just log errors and continue. You can also use the 'error-dump' token which tries to dump core when it sees an error but still continue running. *Note Debug Tokens:.

When a program dumps core, the system writes the program and all of its memory to a file on disk usually named 'core'. If your program is called 'foo' then your system may dump core as 'foo.core'. If you are not getting a 'core' file, make sure that your program has not changed to a new directory meaning that it may have written the core file in a different location. Also insure that your program has write privileges over the directory that it is in otherwise it will not be able to dump a core file. Core dumps are often security problems since they contain all program memory so systems often block their being produced. You will want to check your user and system's core dump size ulimit settings.

The library by default uses the 'abort' function to dump core which may or may not work depending on your operating system. If the following program does not dump core then this may be the problem. See 'KILL_PROCESS' definition in 'settings.dist'.

```c
main()
{
    abort();
}
```

\(^{39}\)http://dmalloc.com/

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
If `abort` does work then you may want to try the following setting in `settings.dist`. This code tries to generate a segmentation fault by dereferencing a `NULL` pointer.

```c
#define KILL_PROCESS { int * _int_p = 0L; * _int_p = 1; }
```

### NULL in C/C++

NULL in C/C++ is just a macro which is often defined like this:

```c
#define NULL ((void*)0)
```

`void*` is a data type reflecting the fact it’s the pointer, but to a value of unknown data type (`void`). NULL is usually used to show absence of an object. For example, you have a single-linked list, and each node has a value (or pointer to a value) and `next` pointer. To show that there are no next node, 0 is stored to `next` field. (Other solutions are just worse.) Perhaps, you may have some crazy environment where you need to allocate memory blocks at zero address. How would you indicate absence of the next node? Some kind of `magic number`? Maybe -1? Or maybe using additional bit?

In Wikipedia we may find this:

> In fact, quite contrary to the zero page’s original preferential use, some modern operating systems such as FreeBSD, Linux and Microsoft Windows[2] actually make the zero page inaccessible to trap uses of NULL pointers.

### Null pointer to function

It’s possible to call function by its address. For example, I compile this by MSVC 2010 and run it in Windows 7:

```c
#include <windows.h>
#include <stdio.h>

int main()
{
    printf ("0x%llx\n", &MessageBoxA);
}
```

The result is `0x7578feae` and doesn’t changing after several times I run it, because `user32.dll` (where `MessageBoxA` function resides) is always loads at the same address. And also because ASLR\(^\text{40}\) is not enabled (result would be different each time in that case).

Let’s call `MessageBoxA()` by address:

```c
#include <windows.h>
#include <stdio.h>

typedef int (*msgboxtype)(HWND hWnd, LPCTSTR lpText, LPCTSTR lpCaption, UINT uType);

int main()
{
    msgboxtype msgboxaddr=0x7578feae;
    // force to load DLL into process memory,
    // since our code doesn't use any function from user32.dll,
    // and DLL is not imported
    LoadLibrary ("user32.dll");
    msgboxaddr(NULL, "Hello, world!", "hello", MB_OK);
```

\(^{40}\)Address Space Layout Randomization

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Weird, but works in Windows 7 x86.
This is commonly used in shellcodes, because it’s hard to call DLL functions by name from there. And ASLR is a countermeasure.

Now what is really weird, some embedded C programmers may be familiar with a code like that:

```c
int reset()
{
    void (*foo)(void) = 0;
    foo();
}
```

Who will want to call a function at address 0? This is portable way to jump at zero address. Many low-cost cheap microcontrollers also have no memory protection or MMU and after reset, they start to execute code at address 0, where some kind of initialization code is stored. So jumping to address 0 is a way to reset itself. One could use inline assembly, but if it’s not possible, this portable method can be used.

It even compiles correctly by my GCC 4.8.4 on Linux x64:

```assembly
reset:
    sub    rsp, 8
    xor    eax, eax
    call   rax
    add    rsp, 8
    ret
```

The fact that stack pointer is shifted is not a problem: initialization code in microcontrollers usually completely ignores registers and RAM state and boots from scratch.

And of course, this code will crash on *NIX or Windows because of memory protection and even in absence of protection, there are no code at address 0.

GCC even has non-standard extension, allowing to jump to a specific address rather than call a function there: [http://gcc.gnu.org/onlinedocs/gcc/Labels-as-Values.html](http://gcc.gnu.org/onlinedocs/gcc/Labels-as-Values.html).

### 3.21.5 Array as function argument

Someone may ask, what is the difference between declaring function argument type as array and as pointer?

As it seems, there are no difference at all:

```c
void write_something1(int a[16])
{
    a[5]=0;
}

void write_something2(int *a)
{
    a[5]=0;
}

int f()
{
    int a[16];
    write_something1(a);
    write_something2(a);
}
```

Optimizing GCC 4.8.4:

```assembly
write_something1:
    mov    DWORD PTR [rdi+20], 0
    ret

write_something2:
```

(For statistics collecting purposes) if you’ve read this far, please click [here](http://gcc.gnu.org/onlinedocs/gcc/Labels-as-Values.html). Thanks!
But you may still declare array instead of pointer for self-documenting purposes, if the size of array is always fixed. And maybe, some static analysis tool will be able to warn you about possible buffer overflow. Or is it possible with some tools today?

Some people, including Linus Torvalds, criticizes this C/C++ feature: https://lkml.org/lkml/2015/9/3/428.

C99 standard also have static keyword [ISO/IEC 9899:TC3 (C C99 standard), (2007) 6.7.5.3]:

> If the keyword static also appears within the [ and ] of the array type derivation, then for each call to the function, the value of the corresponding actual argument shall provide access to the first element of an array with at least as many elements as specified by the size expression.

### 3.21.6 Pointer to a function

A function name in C/C++ without brackets, like “printf” is a pointer to function of void (*)() type. Let’s try to read function’s contents and patch it:

```c
#include <memory.h>
#include <stdio.h>

void print_something ()
{
    printf("we are in \%s()\n", __FUNCTION__);
};

int main()
{
    print_something();
    printf("first 3 bytes: \%x \%x \%x...\n",
            *(unsigned char*)print_something,
            *((unsigned char*)print_something+1),
            *((unsigned char*)print_something+2));
    *(unsigned char*)print_something=0xC3; // RET's opcode
    printf("going to call patched print_something()::\n");
    print_something();
    printf("it must exit at this point\n");
};
```

It tells, that the first 3 bytes of functions are 55 89 e5. Indeed, these are opcodes of PUSH EBP and MOV EBP, ESP instructions (these are x86 opcodes). But then our program crashes, because text section is readonly.

We can recompile our example and make text section writable 41:

```bash
gcc --static -g -Wl,-omagic -o example example.c
```

That works!

```
we are in print_something()
first 3 bytes: 55 89 e5...
going to call patched print_something():
it must exit at this point
```

41 http://stackoverflow.com/questions/27581279/make-text-segment-writable-elf

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
3.21.7 Pointer to a function: copy protection

A software cracker can find a function that checks protection and return true or false. He/she then can put XOR EAX,EAX / RETN or MOV EAX, 1 / RETN there.

Can you check integrity of it? As it turns out, this can be done easily.

According to objdump, the first 3 bytes of check_protection() are 0x55 0x89 0xE5 (given the fact this is non-optimizing GCC):

```c
#include <stdlib.h>
#include <stdio.h>

int check_protection() {
    // do something
    return 0;
    // or return 1;
};

int main() {
    if (check_protection()==0) {
        printf("no protection installed\n");
        exit(0);
    }
    // ...and then, at some very important point...
    if (*((unsigned char*)check_protection)+0) != 0x55) {
        printf("1st byte has been altered\n");
        // do something mean, add watermark, etc
    }
    if (*((unsigned char*)check_protection)+1) != 0x89) {
        printf("2nd byte has been altered\n");
        // do something mean, add watermark, etc
    }
    if (*((unsigned char*)check_protection)+2) != 0xE5) {
        printf("3rd byte has been altered\n");
        // do something mean, add watermark, etc
    }
};
```

If someone would patch check_protection(), your program can do something mean, maybe exit suddenly. To find such a trick, a cracker can set a memory read breakpoint on the address of the function. (tracer has BPMx options for that.)

3.21.8 Pointer as object identifier

Both assembly language and C has no OOP features, but it's possible to write a code in OOP style (just treat structure as an object).

It's interesting, that sometimes, pointer to an object (or its address) is called as ID (in sense of data hiding/encapsulation).

---

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
For example, LoadLibrary(), according to MSDN[^42], returns “handle to the module”[^43]. Then you pass this “handle” to other functions like GetProcAddress(). But in fact, LoadLibrary() returns pointer to DLL file mapped into memory[^44]. You can read two bytes from the address LoadLibrary() returns, and that would be “MZ” (first two bytes of any .EXE/.DLL file in Windows).

Apparently, Microsoft “hides” that fact to provide better forward compatibility. Also, HMODULE and HINSTANCE data types had another meaning in 16-bit Windows.

Probably, this is reason why printf() has “%p” modifier, which is used for printing pointers (32-bit integers on 32-bit architectures, 64-bit on 64-bit, etc) in hexadecimal form. Address of a structure dumped into debug log may help in finding it in another place of log.

Here is also from SQLite source code:

```c
...

struct Pager {
    sqlite3_vfs *pVfs; /* OS functions to use for IO */
    u8 exclusiveMode; /* Boolean. True if locking mode==EXCLUSIVE */
    u8 journalMode; /* One of the PAGER_JOURNALMODE * values */
    u8 useJournal; /* Use a rollback journal on this file */
    u8 noSync; /* Do not sync the journal if true */

    ...

    static int pagerLockDb(Pager *pPager, int eLock){
        int rc = SQLITE_OK;

        assert( eLock==SHARED_LOCK || eLock==RESERVED_LOCK || eLock==EXCLUSIVE_LOCK);
        if( pPager->eLock<eLock || pPager->eLock==UNKNOWN_LOCK ){
            rc = sqlite3OsLock(pPager->fd, eLock);
            if( rc==SQLITE_OK && (pPager->eLock!=UNKNOWN_LOCK||eLock==EXCLUSIVE_LOCK) ){
                pPager->eLock = (u8)eLock;
                IOTRACE(("LOCK %p %d\n", pPager, eLock))
            }
        }
        return rc;
    }

    ...

    PAGER_INCR(sqlite3_pager_readdb_count);
    PAGER_INCR(pPager->nRead);
    IOTRACE("PGIN %p %d\n", pPager, pgno);
    PAGERTRACE("FETCH %d page %d hash(%08x)\n",
                    PAGERID(pPager), pgno, pager_pagehash(pPg));

    ...
```

### 3.21.9 Oracle RDBMS and a simple garbage collector for C/C++

There was a time, when the author of these lines tried to learn more about Oracle RDBMS, searching for vulnerabilities, etc. This is a huge piece of software, and a typical function can take very large nested objects as arguments. And I wanted to dump these objects, as trees (or graphs).

Also, I tracked all memory allocations/deallocations by intercepting memory allocating/deallocating functions. And when a function to be intercepted getting a pointer to a block in memory, I search for the block in a list of blocks allocated. I’m getting its size + short name of block (this is like “tagging” in Windows OS kernel[^45]).

Given a block, I can scan it for 32-bit words (on 32-bit OS) or for 64-bit words (on 64-bit OS). Each word can be a pointer to another block. And if it is so (I find this another block in my records), I can process it...

(For statistics collecting purposes) if you’ve read this far, please click [here](http://yurichev.com/C-book.html). Thanks!
And then, using GraphViz, I could render such a diagrams:

```
Bigger pictures: 1, 2.

This is quite impressive, given the fact that I had no information about data types of all these structures. But I could get some information from it.

**Now the garbage collector for C/C++: Boehm GC**

If you use a block allocated in memory, its address has to be present somewhere, as a pointer in some structure/array in another allocated block, or in globally allocated structure, or in local variable in stack. If there are no pointer to a block, you can call it “orphan”, and it will be a reason of memory leak.

And this is what GC\(^\text{46}\) does. It scans all blocks (because it keep tabs on all blocks allocated) for pointers. It’s important to understand, that it has no idea of data types of all these structure fields in blocks—this is important, GC\(^\text{46}\) has no information about types. It just scans blocks for 32-bit of 64-bit words and see, if they could be a pointers to another block(s). It also scans stack. It treats allocated blocks and stack as arrays of words, some of which may be pointers. And if it found a block allocated, which is “orphaned”, i.e., there are no pointer(s) to it from another block(s) or stack, this block considered unneeded, to be freed. Scanning process takes time, and this is what for GCs are criticized.

Also, GC\(^\text{47}\) like Boehm GC\(^\text{47}\) (for pure C) has function like GC_malloc_atomic()—using it, you declare that the block allocated using this function will never contain any pointer(s) to other block(s). Maybe this could be a text string, or other type of data. (Indeed, GC_strdup() calls GC_malloc_atomic().) GC\(^\text{47}\) will not scan it.

\(^{46}\text{Garbage Collector}\)

\(^{47}\text{https://www.hboehm.info/gc/}\)

(For statistics collecting purposes) if you’ve read this far, please click [here](https://www.hboehm.info/gc/). Thanks!
3.22 Loop optimizations

3.22.1 Weird loop optimization

This is a simplest ever memcpy() function implementation:

```c
void memcpy (unsigned char* dst, unsigned char* src, size_t cnt)
{
    size_t i;
    for (i=0; i<cnt; i++)
        dst[i]=src[i];
}
```

At least MSVC 6.0 from the end of 1990s till MSVC 2013 can produce a really weird code (this listing is generated by MSVC 2013 x86):

```assembly
_dst$ = 8
_src$ = 12
_cnt$ = 16
_memcpy PROC
    mov    edx, DWORD PTR _cnt$[esp-4]
    test   edx, edx
    je     SHORT $LN1@f
    mov    eax, DWORD PTR _dst$[esp-4]
    mov    esi, DWORD PTR _src$[esp]
    mov    esi, eax
    push   esi
    sub    esi, eax
    ; ESI=src-dst, i.e., pointers difference
$LL8@f:
    mov    cl, BYTE PTR [esi+edx] ; load byte at "esi+dst" or at "src-dst+dst" at the beginning or at just "src"
    lea    eax, DWORD PTR [eax+1] ; dst++
    mov    BYTE PTR [eax+1], cl ; store the byte at "(dst)--" or at just "dst" at the beginning
    dec    edx ; decrement counter until we finished
    jne    SHORT $LL8@f
    pop    esi
$LN1@f:
    ret    0
_memcpy ENDP
```

This is weird, because how humans work with two pointers? They store two addresses in two registers or two memory cells. MSVC compiler in this case stores two pointers as one pointer (sliding dst in EAX) and difference between src and dst pointers (left unchanged over the span of loop body execution in ESI). (By the way, this is a rare case when ptrdiff_t data type can be used.) When it needs to load a byte from src, it loads it at diff + sliding dst and stores byte at just sliding dst.

This has to be some optimization trick. But I’ve rewritten this function to:

```assembly
_f2 PROC
    mov    edx, DWORD PTR _cnt$[esp-4]
    test   edx, edx
    je     SHORT $LN1@f
    mov    eax, DWORD PTR _dst$[esp-4]
    mov    esi, DWORD PTR _src$[esp]
    ; eax=dst; esi=src
$LL8@f:
    mov    cl, BYTE PTR [esi+edx] ; load byte at "esi+dst" or at "src-dst+dst" at the beginning or at just "src"
    mov    BYTE PTR [eax+edx], cl ; store the byte at "(dst)--" or at just "dst" at the beginning
    dec    edx ; decrement counter until we finished
    jne    SHORT $LL8@f
    pop    esi
$LN1@f:
    ret    0
_f2 ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
...and it works as efficient as the optimized version on my Intel Xeon E31220 @ 3.10GHz. Maybe, this optimization was targeted some older x86 CPUs of 1990s era, since this trick is used at least by ancient MS VC 6.0?

Any idea?

Hex-Rays 2.2 have a hard time recognizing patterns like that (hopefully, temporary?):

```c
void __cdecl f1(char *dst, char *src, size_t size)
{
    size_t counter; // edx@1
    char *sliding_dst; // eax@2
    char tmp; // ecx@3

    counter = size;
    if (size)
    {
        sliding_dst = dst;
        do
        {
            tmp = (sliding_dst++)[src - dst]; // difference (src-dst) is calculated once, at
            *(sliding_dst - 1) = tmp;
            --counter;
        }
        while (counter);
    }
}
```

Nevertheless, this optimization trick is often used by MSVC (not just in DIY48 homebrew memcpy() routines, but in many loops which uses two or more arrays), so it’s worth for reverse engineers to keep it in mind.

### 3.22.2 Another loop optimization

If you process all elements of some array which happens to be located in global memory, compiler can optimize it. For example, let’s calculate a sum of all elements of array of 128 int’s:

```c
#include <stdio.h>

int a[128];

int sum_of_a()
{
    int rt=0;
    for (int i=0; i<128; i++)
        rt+=a[i];
    return rt;
}

int main()
{
    // initialize
    for (int i=0; i<128; i++)
        a[i]=i;

    // calculate the sum
    printf("%d\n", sum_of_a());
}
```

Optimizing GCC 5.3.1 (x86) can produce this (IDA):

```
000484B0 proc near
000484B0 mov edx, offset a
000484B5 xor eax, eax
000484B7 mov esi, esi
```

48Do It Yourself

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
What the heck is `__libc_start_main@@GLIBC_2_0` at 0x080484C5? This is a label just after end of a[] array. The function can be rewritten like this:

```c
int sum_of_a_v2()
{
    int *tmp=a;
    int rt=0;

    do
    {
        rt=rt+(*tmp);
        tmp++;
    }
    while (tmp<(a+128));

    return rt;
}
```

First version has i counter, and the address of each element of array is to be calculated at each iteration. The second version is more optimized: the pointer to each element of array is always ready and is sliding 4 bytes forward at each iteration. How to check if the loop is ended? Just compare the pointer with the address just behind array's end, which is, in our case, is happens to be address of imported `__libc_start_main()` function from Glibc 2.0. Sometimes code like this is confusing, and this is very popular optimizing trick, so that's why I made this example.

My second version is very close to what GCC did, and when I compile it, the code is almost the same as in first version, but two first instructions are swapped:
Needless to say, this optimization is possible if the compiler can calculate address of the end of array during compilation time. This happens if the array is global and it’s size is fixed.

However, if the address of array is unknown during compilation, but size is fixed, address of the label just behind array’s end can be calculated at the beginning of the loop.

### 3.23 More about structures

#### 3.23.1 Sometimes a C structure can be used instead of array

**Arithmetic mean**

```c
#include <stdio.h>

int mean(int *a, int len)
{
    int sum=0;
    for (int i=0; i<len; i++)
        sum=sum+a[i];
    return sum/len;
}

struct five_ints
{
    int a0;
    int a1;
    int a2;
    int a3;
    int a4;
};

int main()
{
    struct five_ints a;
    a.a0=123;
    a.a1=456;
    a.a2=789;
    a.a3=10;
    a.a4=100;
    printf( "%d\n", mean(&a, 5));
    // test: https://www.wolframalpha.com/input/?i=mean(123,456,789,10,100)
}
```

This works: `mean()` function will never access behind the end of `five_ints` structure, because 5 is passed, meaning, only 5 integers will be accessed.

**Putting string into structure**

```c
#include <stdio.h>

struct five_chars
{
    char a0;
    char a1;
    char a2;
    char a3;
    char a4;
} __attribute__((aligned (1),packed));

int main()
{
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
struct five_chars a;
a.a0='h';
a.a1='i';
a.a2='!';
a.a3='\n';
a.a4=0;
printf (&a); // prints "hi"
};

((aligned (1),packed)) attribute must be used, because otherwise, each structure field will be aligned on
4-byte or 8-byte boundary.

Summary

This is just another example of how structures and arrays are stored in memory. Perhaps, no sane pro-
grammer will do something like in this example, except in case of some specific hack. Or maybe in case
of source code obfuscation?

3.23.2 Unsized array in C structure

In some win32 structures we can find ones with last field defined as an array of one element:

typedef struct _SYMBOL_INFO {
    ULONG SizeOfStruct;
    ULONG TypeIndex;
    ...
    ULONG MaxNameLen;
    TCHAR Name[1];
} SYMBOL_INFO, *PSYMBOL_INFO;

This is a hack, meaning, the last field is array of unknown size, which is to be calculated at the time of
structure allocation.

Why: Name field may be short, so why to define it with some kind of MAX_NAME constant which can be
128, 256, or even bigger?

Why not to use pointer instead? Then you have to allocate two blocks: one for structure and the other
one for string. This may be slower and may require larger memory overhead. Also, you need dereference
pointer (i.e., read address of the string from the structure)—not a big deal, but some people say this is
still surplus cost.

This is also known as struct hack: http://c-faq.com/struct/structhack.html.

Example:

#include <stdio.h>

struct st
{
    int a;
    int b;
    char s[];
};

void f (struct st *s)
{
    printf ("%d %d %s\n", s->a, s->b, s->s);
    // f() can't replace s[] with bigger string - size of allocated block is unknown at this
    point
};

int main()
{
    #define STRING "Hello!"

    (For statistics collecting purposes) if you've read this far, please click here. Thanks!
struct st *s = malloc(sizeof(struct st) + strlen(STRING) + 1);  // incl. terminating zero
s->a = 1;
s->b = 2;
strcpy (s->s, STRING);
f(s);
}

In short, it works because C has no array boundary checks. Any array is treated as having infinite size.

Problem: after allocation, the whole size of allocated block for structure is unknown (except for memory manager), so you can't just replace string with larger string. You would still be able to do so if the field would be declared as something like s[MAX_NAME].

In other words, you have a structure plus an array (or string) fused together in the single allocated memory block. Another problem is what you obviously can't declare two such arrays in single structure, or to declare another field after such array.

Older compilers require to declare array with at least one element: s[1], newer allows to declare it as variable-sized array: s[]. This is also called flexible array member\(^\text{49}\) in C99 standard.

Read more about it in GCC documentation\(^\text{50}\), MSDN documentation\(^\text{51}\).

Dennis Ritchie (one of C creators) called this trick “unwarranted chumminess with the C implementation” (perhaps, acknowledging hackish nature of the trick).

Like it or not, use it or not: it is still another demonstration on how structures are stored in memory, that’s why I write about it.

### 3.23.3 Version of C structure

Many Windows programmers have seen this in MSDN:

<table>
<thead>
<tr>
<th>SizeOfStruct</th>
</tr>
</thead>
<tbody>
<tr>
<td>The size of the structure, in bytes. This member must be set to sizeof(SYMBOL_INFO).</td>
</tr>
</tbody>
</table>

Some structures like SYMBOL_INFO has started with this field indeed. Why? This is some kind of structure version.

Imagine you have a function which draws circle. It takes a single argument—a pointer to a structure with only three fields: X, Y and radius. And then color displays flooded a market, sometimes in 1980s. And you want to add color argument to the function. But, let’s say, you cannot add another argument to it (a lot of software use your API\(^\text{52}\) and cannot be recompiled). And if the old piece of software uses your API with color display, let your function draw a circle in (default) black and white colors.

Another day you add another feature: circle now can be filled, and brush type can be set.

Here is one solution to the problem:

```c
#include <stdio.h>

struct ver1
{
    size_t SizeOfStruct;
    int coord_X;
    int coord_Y;
    int radius;
};

struct ver2
{
    size_t SizeOfStruct;
    int coord_X;
    int coord_Y;
    int radius;
}
```

\(^{49}\)https://en.wikipedia.org/wiki/Flexible_array_member

\(^{50}\)https://gcc.gnu.org/onlinedocs/gcc/Zero-Length.html

\(^{52}\)Application Programming Interface

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
int color;
}

struct ver3
{
    size_t SizeOfStruct;
    int coord_X;
    int coord_Y;
    int radius;
    int color;
    int fill_brush_type; // 0 - do not fill circle
}

void draw_circle(struct ver3 *s) // latest struct version is used here
{
    // we presume SizeOfStruct, coord_X and coord_Y fields are always present
    printf("We are going to draw a circle at \%d:%d\n", s->coord_X, s->coord_Y);

    if (s->SizeOfStruct>=sizeof(int)*5)
    {
        // this is at least ver2, color field is present
        printf("We are going to set color \%d\n", s->color);
    }

    if (s->SizeOfStruct>=sizeof(int)*6)
    {
        // this is at least ver3, fill brush type field is present
        printf("We are going to fill it using brush type \%d\n", s->fill_brush_type);
    }
}

// early software version
void call_as_ver1()
{
    struct ver1 s;
    s.SizeOfStruct=sizeof(s);
    s.coord_X=123;
    s.coord_Y=456;
    s.radius=10;
    printf("** %s\n", __FUNCTION__);
    draw_circle(&s);
}

// next software version
void call_as_ver2()
{
    struct ver2 s;
    s.SizeOfStruct=sizeof(s);
    s.coord_X=123;
    s.coord_Y=456;
    s.radius=10;
    s.color=1;
    printf("** %s\n", __FUNCTION__);
    draw_circle(&s);
}

// latest, most advanced version
void call_as_ver3()
{
    struct ver3 s;
    s.SizeOfStruct=sizeof(s);
    s.coord_X=123;
    s.coord_Y=456;
    s.radius=10;
    s.color=1;
    s.fill_brush_type=3;
    printf("** %s\n", __FUNCTION__);
    draw_circle(&s);
}
```c
int main()
{
    call_as_ver1();
    call_as_ver2();
    call_as_ver3();
}
```

In other words, `SizeOfStruct` field takes a role of `version of structure` field. It could be enumerate type (1, 2, 3, etc.), but to set `SizeOfStruct` field to `sizeof(struct...)` is less prone to mistakes/bugs: we just write `s.SizeOfStruct=sizeof(...)` in caller's code.

In C++, this problem is solved using `inheritance` (3.19.1 on page 554). You just extend your base class (let's call it `Circle`), and then you will have `ColoredCircle` and then `FilledColoredCircle`, and so on. A current `version` of an object (or, more precisely, current `type`) will be determined using C++ `RTTI`.

So when you see `SizeOfStruct` somewhere in `MSDN`—perhaps this structure was extended at least once in past.

### 3.23.4 High-score file in “Block out” game and primitive serialization

Many videogames has high-score file, sometimes called “Hall of fame”. Ancient “Block out”[^53] game (3D tetris from 1989) isn’t exception, here is what we see at the end:

![High score table](http://www.bestoldgames.net/eng/old-games/blockout.php)

Figure 3.4: High score table

Now we can see that the file has changed after we added our name is `BLSCORE.DAT`.

```
% xxd -g 1 BLSCORE.DAT

00000000: 0a 00 58 6e 69 61 2e 2e 2e 2e 2e 2e 00 df 01 00 ..Xenia........
00000010: 00 30 33 2d 32 37 2d 32 30 31 38 00 50 61 75 6c .03-27-2018.Paul
00000020: 2e 2e 2e 2e 2e 00 61 01 00 00 30 33 2d 32 37 2d 2e 2e 2e 2e -2018.John......

00000050: 00 46 01 00 00 30 33 2d 32 37 2d 32 30 31 38 00 50 61 72 79 2e 2e 2e 2e 00 00 00 00 ...
00000060: 50 61 72 79 2e 2e 2e 2e 00 4d 69 6b 65 2e 2e 2e 2e 00 00 00 00 00 00 00 00 00 00 00 ...03-27-2018.Mike......
00000070: 01 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
00000080: 01 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
00000090: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000a0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000b0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000c0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000d0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000e0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
000000f0: 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 ...
```

(For statistics collecting purposes) if you’ve read this far, please click [here](http://www.bestoldgames.net/eng/old-games/blockout.php). Thanks!
All entries are clearly visible. The very first byte is probably number of entries. Second is zero and, in fact, number of entries can be 16-bit value spanning over first two bytes.

Next, after “Xenia” name we see 0xDF and 0x01 bytes. Xenia has score of 479, and this is exactly 0x1DF in hexadecimal radix. So a high score value is probably 16-bit integer, or maybe 32-bit integer: there are two more zero bytes after.

Now let’s think about the fact that both array elements and structure elements are always placed in memory adjacently to each other. That enables us to write the whole array/structure to the file using simple `write()` or `fwrite()` function, and then restore it using `read()` or `fread()`, as simple as that. This is what is called serialization nowadays.

**Read**

Now let’s write C program to read highscore file:

```c
#include <cassert.h>
#include <stdio.h>
#include <stdint.h>
#include <string.h>

struct entry
{
    char name[11]; // incl. terminating zero
    uint32_t score;
    char date[11]; // incl. terminating zero
} __attribute__((aligned(1),packed));

struct highscore_file
{
    uint8_t count;
    uint8_t unknown;
    struct entry entries[10];
} __attribute__((aligned(1), packed));

struct highscore_file file;

int main(int argc, char* argv[])
{
    FILE* f=fopen(argv[1], "rb");
    assert (f!=NULL);
    size_t got=fread(&file, 1, sizeof(struct highscore_file), f);
    assert (got==sizeof(struct highscore_file));
    fclose(f);
    for (int i=0; i<file.count; i++)
    {
        printf("name=%s score=%d date=%s\n",
               file.entries[i].name,
               file.entries[i].score,
               file.entries[i].date);
    }
}
```

We need GCC `((aligned (1),packed))` attribute so that all structure fields will be packed on 1-byte boundary.

Of course it works:

```
name=Xenia..... score=479 date=03-27-2018
name=Paul....... score=353 date=03-27-2018
name=John....... score=326 date=03-27-2018
name=James....... score=324 date=03-27-2018
name=Charlie... score=234 date=03-27-2018
name=Mike...... score=181 date=03-27-2018
name=Phil....... score=172 date=03-27-2018
name=Mary...... score=123 date=03-27-2018
name=Tom....... score=119 date=03-27-2018
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
(Needless to say, each name is padded with dots, both on screen and in the file, perhaps, for æsthetical reasons.)

Write

Let's check if we right about width of score value. Is it really has 32 bits?

```c
int main(int argc, char* argv[])
{
    FILE* f=fopen(argv[1], "rb");
    assert (f!=NULL);
    size_t got=fopen(&file, 1, sizeof(struct highscore_file), f);
    assert (got==sizeof(struct highscore_file));
    fclose(f);

    strcpy (file.entries[1].name, "Mallory...");
    file.entries[1].score=12345678;
    strcpy (file.entries[1].date, "08-12-2016");

    f=fopen(argv[1], "wb");
    assert (f!=NULL);
    got=fwrite(&file, 1, sizeof(struct highscore_file), f);
    assert (got==sizeof(struct highscore_file));
    fclose(f);
}
```

Let's run Blockout:

![Hall of Fame](image)

Figure 3.5: High score table

First two digits (1 and 2) are truncated: 12345678 becomes 345678. Perhaps, this is formatting issues... but the number is almost correct. Now I'm changing it to 999999 and run again:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Now it’s correct. Yes, high score value is 32-bit integer.

**Is it serialization?**

...almost. Serialization like this is highly popular in scientific and engineering software, where efficiency and speed is much more important than converting into *XML* or *JSON* and back.

One important thing is that you obviously cannot serialize pointers, because each time you load the file into memory, all the structures may be allocated in different places.

But: if you work on some kind of low-cost MCU with simple OS on it and you have your structures allocated at always same places in memory, perhaps you can save and restore pointers as well.

**Random noise**

When I prepared this example, I had to run “Block out” many times and played for it a bit to fill high-score table with random names.

And when there were just 3 entries in the file, I saw this:

```
00000000: 03 00 54 6f 6d 61 73 2e 2e 2e 2e 2e 00 da 2a 00 ..Tomas.......*.

```

The first byte has value of 3, meaning there are 3 entries. And there are 3 entries present. But then we see a random noise at the second half of file.

---

54Extensible Markup Language  
55JavaScript Object Notation
The noise is probably has its origins in uninitialized data. Perhaps, “Block out” allocated memory for 10 entries somewhere in heap, where, obviously, some pseudorandom noise (left from something else) was present. Then it set first/second byte, fill 3 entries, and then it never touched 7 entries left, so they are written to the file as is.

When “Block out” loads high score file at the next run, it reads number of entries from the first/second byte (3) and then completely ignores what is after it.

This is common problem. Not a problem in strict sense: it’s not a bug, but information can be exposed outwards.

Microsoft Word versions from 1990s has been often left pieces of previously edited texts into the *.doc* files. It was some kind of amusement back then, to get a .doc file from someone, then open it in a hexadecimal editor and read something else, what has been edited on that computer before.

The problem can be even much more serious: Heartbleed bug\(^56\) in OpenSSL.

### Homework

“Block out” has several polycubes (flat/basic/extended), size of pit can be configured, etc. And it seems, for each configuration, “Block out” has its own high score table. I’ve noticed that some information is probably stored in BLSCORE.IDX file. This can be a homework for hardcore “Block out” fans—to understand its structure as well.

The “Block out” files are here: [http://beginners.re/examples/blockout.zip](http://beginners.re/examples/blockout.zip) (including the binary high score files I’ve used in this example). You can use DosBox to run it.

#### 3.24 memmove() and memcpy()

The difference between these standard functions is that memcpy() blindly copies a block to another place, while memmove() correctly handles overlapping blocks. For example, you want to tug a string two bytes forward:

```
|.|.|h|e|l|l|o|...` -> `|h|e|l|l|o|...`
```

memcpy() which copies 32-bit or 64-bit words at once, or even SIMD, will obviously fail here, a byte-wise copy routine must be used instead.

Now even more advanced example, insert two bytes in front of string:

```
|h|e|l|l|o|...` -> `|.|.|h|e|l|l|o|...`
```

Now even byte-wise memory copy routine will fail, you have to copy bytes starting at the end.

That’s a rare case where DF x86 flag is to be set before REP MOVSB instruction: DF defines direction, and now we must move backwardly.

The typical memmove() routine works like this: 1) if source is below destination, copy forward; 2) if source is above destination, copy backward.

This is memmove() from uClibc:

```c
void *memmove(void *dest, const void *src, size_t n)
{
    int eax, ecx, esi, edi;
    __asm__ volatile(_asm);
        movl %eax, %edi
        cmpl %esi, %eax
        je 2f
        jb 1f /* (optional) src == dest -> NOP */
        leal -1(%esi,%ecx), %esi
        leal -1(%eax,%ecx), %edi
        std
        "1:"
            rep; movsb
        "2:"cld
}
```

\(^56\)https://en.wikipedia.org/wiki/Heartbleed

(For statistics collecting purposes) if you’ve read this far, please click [here](http://beginners.re/examples/blockout.zip). Thanks!
In the first case, REP MOVSB is called with DF flag cleared. In the second, DF is set, then cleared.
More complex algorithm has the following piece in it:

“if difference between source and destination is larger than width of word, copy using words rather than bytes, and use byte-wise copy to copy unaligned parts”.

This how it happens in Glibc 2.24 in non-optimized C part.

Given all that, memmove() may be slower than memcpy(). But some people, including Linus Torvalds, argue that memcpy() should be an alias (or synonym) of memmove(), and the latter function must just check at start, if the buffers are overlapping or not, and then behave as memcpy() or memmove(). Nowadays, check for overlapping buffers is very cheap, after all.

### 3.24.1 Anti-debugging trick

I've heard about anti-debugging trick where all you need is just set DF to crash the process: the very next memcpy() routine will lead to crash because it copies backwardly. But I can't check this: it seems all memory copy routines clear/set DF as they want to. On the other hand, memmove() from uClibc I cited here, has no explicit clear of DF (it assumes DF is always clear?), so it can really crash.

### 3.25 setjmp/longjmp

setjmp/longjmp is a mechanism in C which is very similar to throw/catch mechanism in C++ and other higher-level PLs. Here is an example from zlib:

```c
/* return if bits() or decode() tries to read past available input */
if (setjmp(s.env) != 0) {          /* if came back here via longjmp(), */
    err = 2;                      /* then skip decompress(), return error */
} else {                           /* decompress */
    err = decompress(&s);        /* decompress */
}

/* load at least need bits into val */
val = s->bitbuf;
while (s->bitcnt < need) {
    if (s->left == 0) {
        s->left = s->infun(s->inhow, &s->in);
        if (s->left == 0) longjmp(s->env, 1); /* out of input */
    }
}
```

( zlib/contrib/blast/blast.c )

Call to setjmp() saves current PC, SP and other registers into env structure, then it returns 0.
In case of error, longjmp() teleporting you into the point after right after setjmp() call, as if setjmp() call returned non-null value (which was passed to longjmp()). This reminds as fork() syscall in UNIX.

Now let's take a look on distilled example:

57 https://bugzilla.redhat.com/show_bug.cgi?id=638477#c132
```c
#include <stdio.h>
#include <setjmp.h>

jmp_buf env;

void f2()
{
    printf("%s() begin\n", __FUNCTION__);
    // something odd happened here
    longjmp(env, 1234);
    printf("%s() end\n", __FUNCTION__);
}

void f1()
{
    printf("%s() begin\n", __FUNCTION__);
    f2();
    printf("%s() end\n", __FUNCTION__);
}

int main()
{
    int err=setjmp(env);
    if (err==0)
    {
        f1();
    }
    else
    {
        printf("Error %d\n", err);
    }
}

If we run it, we will see:

f1() begin
f2() begin
Error 1234

jmp_buf structure usually comes undocumented, to preserve forward compatibility.

Let’s see how setjmp() implemented in MSVC 2013 x64:

...  
; RCX = address of jmp_buf

mov [rcx], rax
mov [rcx+8], rbx
mov [rcx+10h], rbp
mov [rcx+20h], rsi
mov [rcx+28h], rdi
mov [rcx+30h], r12
mov [rcx+38h], r13
mov [rcx+40h], r14
mov [rcx+48h], r15
lea r8, [rsp+arg_0]  ; get saved RA from stack
mov [rcx+50h], r8    ; save it
stmxcsr dword ptr [rcx+58h]
fnstcw word ptr [rcx+5Ch]
movdqa xmmword ptr [rcx+60h], xmm6
movdqa xmmword ptr [rcx+70h], xmm7
movdqa xmmword ptr [rcx+80h], xmm8
movdqa xmmword ptr [rcx+90h], xmm9
movdqa xmmword ptr [rcx+100h], xmm10
movdqa xmmword ptr [rcx+110h], xmm11
movdqa xmmword ptr [rcx+120h], xmm12
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
It just populates jmp_buf structure with current values of almost all registers. Also, current value of RA is taken from the stack and saved in jmp_buf: it will be used as new value of PC in future.

Now longjmp():

```assembly
...  
; RCX = address of jmp_buf
mov  rax, rdx  
mov  rbx, [rcx+8]  
mov  rsi, [rcx+20h]  
mov  rdi, [rcx+28h]  
mov  r12, [rcx+30h]  
mov  r13, [rcx+38h]  
mov  r14, [rcx+40h]  
mov  r15, [rcx+48h]  
ldmxcsr dword ptr [rcx+58h]  
fnclex  
fldcw  word ptr [rcx+5Ch]  
movdqa xmm6, xmmword ptr [rcx+60h]  
movdqa xmm7, xmmword ptr [rcx+70h]  
movdqa xmm8, xmmword ptr [rcx+80h]  
movdqa xmm9, xmmword ptr [rcx+90h]  
movdqa xmm10, xmmword ptr [rcx+0A0h]  
movdqa xmm11, xmmword ptr [rcx+0B0h]  
movdqa xmm12, xmmword ptr [rcx+0C0h]  
movdqa xmm13, xmmword ptr [rcx+0D0h]  
movdqa xmm14, xmmword ptr [rcx+0E0h]  
movdqa xmm15, xmmword ptr [rcx+0F0h]  
mov  rdx, [rcx+50h]  ; get PC (RIP)  
mov  rbp, [rcx+18h]  
mov  rsp, [rcx+10h]  
jmp  rdx  ; jump to saved PC  
...
```

It just restores (almost) all registers, takes RA from structure and jumps there. This effectively works as if setjmp() returned to caller. Also, RAX is set to be equal to the second argument of longjmp(). This works as if setjmp() returned non-zero value at first place.

As a side effect of SP restoration, all values in stack which has been set and used between set jmp() and long jmp() calls are just dropped. They will not be used anymore. Hence, long jmp() usually jumps backwards.

This implies that, unlike in throw/catch mechanism in C++, no memory will be freed, no destructors will be called, etc. Hence, this technique sometimes can be dangerous. Nevertheless, it’s still quite popular. It’s still used in Oracle RDBMS.

It also has unexpected side-effect: if some buffer has been overflown inside of a function (maybe due to remote attack), and a function wants to report error, and it calls long jmp(), overwritten stack part just gets unused.

As an exercise, you can try to understand, why not all registers are saved. Why XMM0-XMM5 and other registers are skipped?

However, there are some people who can use it for much more complicated things, imitating coroutines, etc: [https://www.embeddedrelated.com/showarticle/455.php](https://www.embeddedrelated.com/showarticle/455.php), [http://fanf.livejournal.com/105413.html](http://fanf.livejournal.com/105413.html)

(For statistics collecting purposes) if you’ve read this far, please click [here](https://www.embeddedrelated.com/showarticle/455.php). Thanks!
3.26 Other weird stack hacks

3.26.1 Accessing arguments/local variables of caller

From C/C++ basics we know that this is impossible for a function to access arguments of caller function or its local variables.

Nevertheless, it’s possible using dirty hacks. For example:

```c
#include <stdio.h>

void f(char *text)
{
    // print stack
    int *tmp=&text;
    for (int i=0; i<20; i++)
    {
        printf ("0x%hn", *tmp);
        tmp++;
    }
};

void draw_text(int X, int Y, char* text)
{
    f(text);
    printf ("We are going to draw [%s] at %d:%d\n", text, X, Y);
};

int main()
{
    printf ("address of main()=0x%hn", &main);
    printf ("address of draw_text()=0x%hn", &draw_text);
    draw_text(100, 200, "Hello!");
};
```

On 32-bit Ubuntu 16.04 and GCC 5.4.0, I got this:

```
address of main()=0x80484f8
address of draw_text()=0x80484cb
0x8048645 first argument to f()
0x8048628
0xbfd8ab98
0xb7634590
0xb779eddc
0xb77e4918
0xbfd8aba8
0xb8048547 return address into the middle of main()
0x64 first argument to draw_text()
0xc8 second argument to draw_text()
0x8048645 third argument to draw_text()
0x8048581
0xb779d3dc
0xbfd8abc0
0x0
0xb7603637
0xb779d000
0xb779d000
0x0
0xb7603637
```

(Comments are mine.)

Since `f()` starting to enumerate stack elements at its first argument, the first stack element is indeed a pointer to "Hello!" string. We see its address is also used as third argument to `draw_text()` function.

In `f()` we could read all functions arguments and local variables if we know exact stack layout, but it’s always changed, from compiler to compiler. Various optimization levels affect stack layout greatly.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
But if we can somehow detect information we need, we can use it and even modify it. As an example, I’ll rework f() function:

```c
void f(char *text) {
    ...  
    // find 100, 200 values pair and modify the second on
    tmp=&text;
    for (int i=0; i<20; i++)
    {
        if (*tmp==100 && *(tmp+1)==200)
            {printf ("found\n");  
             *(tmp+1)=210;  // change 200 to 210
             break;  
             tmp++;  
             }
    }
};
```

Holy moly, it works:

found  
We are going to draw [Hello!] at 100:210  

Summary

It’s extremely dirty hack, intended to demonstrate stack internals. I never ever seen or heard that anyone used this in a real code. But still, this is a good example.

Exercise

The example has been compiled without optimization on 32-bit Ubuntu using GCC 5.4.0 and it works. But when I turn on -O3 maximum optimization, it’s failed. Try to find why.

Use your favorite compiler and OS, try various optimization levels, find if it works and if it doesn’t, find why.

3.26.2 Returning string

This is classic bug from Brian W. Kernighan, Rob Pike, *Practice of Programming*, (1999):

```c
#include <stdio.h>

char* amsg(int n, char* s)
{
    char buf[100];
    sprintf (buf, "error %d: %s\n", n, s);
    return buf;
};

int main()
{
    printf ("%s\n", amsg (1234, "something wrong!"));
};
```

It would crash. First, let’s understand, why.

This is a stack state before amsg() return:
When amsg() returns control flow to main(), so far so good. But printf() is called from main(), which
is, in turn, use stack for its own needs, zapping 100-byte buffer. A random garbage will be printed at the
best.

Hard to believe, but I know how to fix this problem:

```c
#include <stdio.h>

char* amsg(int n, char* s)
{
    char buf[100];
    sprintf(buf, "error %d: %s\n", n, s);  // make use of local array.
    return buf;
}

char* interim (int n, char* s)
{
    char large_buf[8000];
    // it will be optimized away otherwise, as useless.
    large_buf[0]=0;
    return amsg(n, s);
}

int main()
{
    printf("%s\n", interim(1234, "something wrong"));
}
```

It will work if compiled by MSVC 2013 with no optimizations and with /GS- option. MSVC will warn:
"warning C4172: returning address of local variable or temporary", but the code will run and message will
be printed. Let’s see stack state at the moment when amsg() returns control to interim():

Now the stack state at the moment when interim() returns control to main():

---

59Turn off buffer security check

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
... [amsg(): 100 bytes] [RA] [two amsg() arguments] [interim() stuff, incl. 8000 bytes] [something else] <- current SP [main() local variables]

(upper addresses)

So when main() calls printf(), it uses stack at the place where interim()’s buffer was allocated, and doesn’t zap 100 bytes with error message inside, because 8000 bytes (or maybe much less) is just enough for everything printf() and other descending functions do!

It may also work if there are many functions between, like: main() → f1() → f2() → f3() ... → amsg(), and then the result of amsg() is used in main(). The distance between SP in main() and address of buf[] must be long enough,

This is why bugs like these are dangerous: sometimes your code works (and bug can be hiding unnoticed), sometimes not. Bugs like these are jokingly called heisenbugs or schrödinbugs.60

### 3.27 OpenMP

OpenMP is one of the simplest ways to parallelize simple algorithms.

As an example, let’s try to build a program to compute a cryptographic nonce.

In my simplistic example, the nonce is a number added to the plain unencrypted text in order to produce a hash with some specific features.

For example, at some step, the Bitcoin protocol requires to find such nonce so the resulting hash contains a specific number of consecutive zeros. This is also called “proof of work” (i.e., the system proves that it did some intensive calculations and spent some time for it).

My example is not related to Bitcoin in any way, it will try to add numbers to the “hello, world!_<number>” string in order to find such number that when “hello, world!_<number>” is hashed with the SHA512 algorithm, it will contain at least 3 zero bytes.

Let’s limit our brute-force to the interval in 0..INT32_MAX-1 (i.e., 0x7FFFFFFE or 2147483646).

The algorithm is pretty straightforward:

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <time.h>
#include "sha512.h"

int found=0;
int32_t checked=0;

int32_t* __min;
int32_t* __max;

time_t start;

#ifdef __GNUC__
#define min(X,Y) ((X) < (Y) ? (X) : (Y))
#define max(X,Y) ((X) > (Y) ? (X) : (Y))
#endif

void check_nonce (int32_t nonce)
```

---

61[wikipedia](https://wikipedia)
The `check_nonce()` function just adds a number to the string, hashes it with the SHA512 algorithm and checks for 3 zero bytes in the result.

A very important part of the code is:

```c
#pragma omp parallel for
for (i=0; i<INT32_MAX; i++)
    check_nonce (i);
```
check_nonce (i);

Yes, that simple, without #pragma we just call check_nonce() for each number from 0 to INT32_MAX (0x7fffffff or 2147483647). With #pragma, the compiler adds some special code which slices the loop interval into smaller ones, to run them on all CPU cores available 62.

The example can be compiled 63 in MSVC 2012:

```
click openmp_example.c sha512.obj /openmp /O1 /Zi /Faopenmp_example.asm
```

Or in GCC:

```
gcc -fopenmp 2.c sha512.c -S -masm=intel
```

### 3.27.1 MSVC

Now this is how MSVC 2012 generates the main loop:

Listing 3.123: MSVC 2012

```
push OFFSET _main$omp$1
push 0
push 1
call __vcomp_fork
add esp, 16
```

All functions prefixed by vcomp are OpenMP-related and are stored in the vcomp*.dll file. So here a group of threads is started.

Let's take a look on _main$omp$1:

Listing 3.124: MSVC 2012

```
$T1 = -8 ; size = 4
$T2 = -4 ; size = 4
_main$omp$1 PROC
  push ebp
  mov ebp, esp
  push ecx
  push ecx
  push esi
  lea eax, DWORD PTR $T2[ebp]
  push eax
  lea eax, DWORD PTR $T1[ebp]
  push eax
  push 1
  push 1
  push 2147483646 ; 7ffffffeH
  push 0
  call __vcomp_for_static_simple_init
  mov esi, DWORD PTR $T1[ebp]
  add esp, 24
  jmp SHORT $LN6@main$omp$1
$LL2@main$omp$1:
  push esi
  call _check_nonce
  pop ecx
  inc esi
$LN6@main$omp$1:
  cmp esi, DWORD PTR $T2[ebp]
  jle SHORT $LL2@main$omp$1
  call __vcomp_for_static_end
  pop esi
  leave
  ret 0
_main$omp$1 ENDP
```

N.B.: This is intentionally simplest possible example, but in practice, the usage of OpenMP can be harder and more complex.

sha512.(c|h) and u64.h files can be taken from the OpenSSL library: [http://go.yurichev.com/17324](http://go.yurichev.com/17324)

(For statistics collecting purposes) if you've read this far, please click [here](http://go.yurichev.com/17324). Thanks!
This function is to be started $n$ times in parallel, where $n$ is the number of CPU cores. 

vcomp_for_static_simple_init() calculates the interval for the for() construct for the current thread, depending on the current thread's number.

The loop's start and end values are stored in the $T1$ and $T2$ local variables. You may also notice 7fffffffeh (or 2147483646) as an argument to the vcomp_for_static_simple_init() function—this is the number of iterations for the whole loop, to be divided evenly.

Then we see a new loop with a call to the check_nonce() function, which does all the work.

Let's also add some code at the beginning of the check_nonce() function to gather statistics about the arguments with which the function has been called.

This is what we see when we run it:

```
threads=4
...
checked=2800000
checked=3000000
checked=3200000
checked=3300000
found (thread 3): [hello, world!_1611446522]. seconds spent=3
__min[0]=0x00000000 __max[0]=0x1fffffff
__min[1]=0x20000000 __max[1]=0x3fffffff
__min[2]=0x40000000 __max[2]=0x5fffffff
__min[3]=0x60000000 __max[3]=0x7fffffff
```

Yes, the result is correct, the first 3 bytes are zeros:

```
C:\...\sha512sum test
000000f4a8fac5a4ed38794da4c1e39f54279ada5d9bb3c5465c6f57adaf60403

```

The running time is ≈ 2.3 seconds on 4-core Intel Xeon E3-1220 3.10 GHz. In the task manager we see 5 threads: 1 main thread + 4 more. No further optimizations are done to keep this example as small and clear as possible. But probably it can be done much faster. My CPU has 4 cores, that is why OpenMP started exactly 4 threads.

By looking at the statistics table we can clearly see how the loop has been sliced into 4 even parts. Oh well, almost even, if we don't consider the last bit.

There are also pragmas for atomic operations.

Let's see how this code is compiled:

```
#pragma omp atomic
    checked++;

#pragma omp critical
if ((checked % 100000)==0)
    printf("checked=%d\n", checked);
```

```
push  edi
push OFFSET _checked
call _vcomp_atomic_add_i4
; Line 55
push OFFSET _vcomp$critsect$
call _vcomp_enter_critsect
add esp, 12
; Line 56
mov  ecx, DWORD PTR _checked
mov  eax, ecx
cdq
mov  esi, 100000 ; 000186a0H
idiv esi
test edx, edx
jne SHORT $LN1@check_nonce
; Line 57
push  ecx
push OFFSET ??_@0M@NPNH2100@checked?@DN?$CFd?6?$AA@
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As it turns out, the `vcomp_atomic_add_i4()` function in the vcomp*.dll is just a tiny function with the LOCK XADD instruction\(^{64}\) in it.

`vcomp_enter_critsect()` eventually calling win32 API function `EnterCriticalSection()`\(^{65}\).

### 3.27.2 GCC

GCC 4.8.1 produces a program which shows exactly the same statistics table, so, GCC’s implementation divides the loop in parts in the same fashion.

#### Listing 3.126: GCC 4.8.1

```
mov    edi, OFFSET FLAT:main._omp_fn.0
call   GOMP_parallel_start
mov    edi, 0
call   main._omp_fn.0
call   GOMP_parallel_end
```

Unlike MSVC’s implementation, what GCC code does is to start 3 threads, and run the fourth in the current thread. So there are 4 threads instead of the 5 in MSVC.

Here is the `main._omp_fn.0` function:

#### Listing 3.127: GCC 4.8.1

```
main._omp_fn.0:
    push   rbp
    mov    rbp, rsp
    push   rbx
    sub     rsp, 40
    mov    QWORD PTR [rbp-40], rdi
    call   omp_get_num_threads
    mov    ebx, eax
    call   omp_get_thread_num
    mov    esi, eax
    mov    eax, 2147483647 ; 0x7FFFFFFF
    cdq
    idiv   ebx
    mov    ecx, eax
    mov    eax, 2147483647 ; 0x7FFFFFFF
    cdq
    idiv   ebx
    mov    eax, edx
    cmp    esi, eax
    jl     .L15
    .L18:
    imul    esi, ecx
    mov    edx, esi
    add    eax, edx
    lea    ebx, [rax+rcx]
    cmp    eax, ebx
    jge    .L14
    mov    DWORD PTR [rbp-20], eax
    .L17:
    mov    eax, DWORD PTR [rbp-20]
    mov    edi, eax
    call   check_nonce
```

\(^{64}\)Read more about LOCK prefix: \textcolor{red}{.1.6 on page 999}

\(^{65}\)You can read more about critical sections here: \textcolor{red}{6.5.4 on page 787}

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Here we see the division clearly: by calling `omp_get_num_threads()` and `omp_get_thread_num()` we get the number of threads running, and also the current thread’s number, and then determine the loop’s interval. Then we run `check_nonce()`.

GCC also inserted the `lock add` instruction right in the code, unlike MSVC, which generated a call to a separate DLL function:

```assembly
lock add DWORD PTR checked[rip], 1
call GOMP_critical_start
mov ecx, DWORD PTR checked[rip]
mov edx, 351843721
mov eax, ecx
imul edx
sar edx, 13
mov eax, ecx
sar eax, 31
sub edx, eax
mov eax, edx
imul eax, eax, 100000
sub ecx, eax
mov eax, ecx
test eax, eax
jne .L7
mov eax, DWORD PTR checked[rip]
mov esi, eax
mov edi, OFFSET FLAT:.LC2 ; "checked=%d\n"
mov eax, 0
call printf
.L7:
call GOMP_critical_end
```

The functions prefixed with GOMP are from GNU OpenMP library. Unlike vcomp*.dll, its source code is freely available: [GitHub](https://github.com).

### 3.28 Another heisenbug

Sometimes, array (or buffer) can overflow due to fencepost error:

```c
#include <stdio.h>

int array1[128];
int important_var1;
int important_var2;
int important_var3;
int important_var4;
int important_var5;

int main()
{
    important_var1=1;
}
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
```c

important_var2=2;
important_var3=3;
important_var4=4;
important_var5=5;

array1[0]=123;
array1[128]=456; // BUG

printf ("important_var1=%d\n", important_var1);
printf ("important_var2=%d\n", important_var2);
printf ("important_var3=%d\n", important_var3);
printf ("important_var4=%d\n", important_var4);
printf ("important_var5=%d\n", important_var5);

}
```

This is what this program printed in my case (non-optimized GCC 5.4 x86 on Linux):

```
important_var1=1
important_var2=456
important_var3=3
important_var4=4
important_var5=5
```

As it happens, important_var2 has been placed by compiler right after array1[]:

```
Listing 3.129: objdump -x
```

```
0804a040 g 0 .bss 00000200 array1
...
0804a240 g 0 .bss 00000004 important_var2
0804a244 g 0 .bss 00000004 important_var4
...
0804a248 g 0 .bss 00000004 important_var1
0804a24c g 0 .bss 00000004 important_var3
0804a250 g 0 .bss 00000004 important_var5
```

Another compiler can arrange variables in another order, and another variable would be zapped. This is also heisenbug (3.26.2 on page 638)—bug may appear or may left unnoticed depending on compiler version and optimization switches.

If all variables and arrays are allocated in local stack, stack protection may be triggered, or may not. However, Valgrind can find bugs like these.

Related example in the book (Angband game): 1.27 on page 305.

### 3.29 The case of forgotten return

Let’s revisit the “attempt to use the result of a function returning void” part: .

This is a bug I once hit.

And this is also yet another demonstration, how C/C++ places return value into EAX/RAX register.

In the piece of code like that, I forgot to add return:

```c
#include <stdio.h>
#include <stdlib.h>

struct color
{
    int R;
    int G;
    int B;
};

struct color* create_color (int R, int G, int B)
{
    struct color* rt=(struct color*)malloc(sizeof(struct color));
    ```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
rt->R=R;
rt->G=G;
rt->B=B;
    // must be "return rt;" here
};

int main()
{
    struct color* a=create_color(1,2,3);
    printf("%d %d %d\n", a->R, a->G, a->B);
};

Non-optimizing GCC 5.4 silently compiles this with no warnings. And the code works! Let’s see, why:

Listing 3.130: Non-optimizing GCC 5.4

create_color:
    push rbp
    mov rbp, rsp
    sub rsp, 32
    mov DWORD PTR [rbp-20], edi
    mov DWORD PTR [rbp-24], esi
    mov DWORD PTR [rbp-28], edx
    mov edi, 12
    call malloc
    ; RAX is pointer to newly allocated buffer
    ; now fill it with R/G/B:
    mov QWORD PTR [rbp-8], rax
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-20]
   mov DWORD PTR [rax], edx
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-24]
    mov DWORD PTR [rax+4], edx
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-28]
    mov DWORD PTR [rax+8], edx
    nop
    leave
    ; RAX wasn’t modified till that point!
    ret

If I add return rt;, the only instruction is added at the end, which is redundant:

Listing 3.131: Non-optimizing GCC 5.4

create_color:
    push rbp
    mov rbp, rsp
    sub rsp, 32
    mov DWORD PTR [rbp-20], edi
    mov DWORD PTR [rbp-24], esi
    mov DWORD PTR [rbp-28], edx
    mov edi, 12
    call malloc
    ; RAX is pointer to buffer
    mov QWORD PTR [rbp-8], rax
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-20]
    mov DWORD PTR [rax], edx
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-24]
    mov DWORD PTR [rax+4], edx
    mov rax, QWORD PTR [rbp-8]
    mov edx, DWORD PTR [rbp-28]
    mov DWORD PTR [rax+8], edx
    ; reload pointer to RAX again, and this is redundant operation...
    mov rax, QWORD PTR [rbp-8] ; new instruction
    leave
    ret
Bugs like that are very dangerous, sometimes they appear, sometimes hide. It’s like Heisenbug.

Now I’m trying optimizing GCC:

```
create_color:
    rep ret
main:
    xor eax, eax
    ; as if create_color() was called and returned 0
    sub rsp, 8
    mov r8d, DWORD PTR ds:8
    mov ecx, DWORD PTR [rax+4]
    mov edx, DWORD PTR [rax]
    mov esi, OFFSET FLAT:.LC1
    mov edi, 1
    call __printf_chk
    xor eax, eax
    add rsp, 8
    ret
```

Compiler deducing that nothing returns from the function, so it optimizes it away. And it assumes, that is returns 0 by default. The zero is then used as an address to a structure in main(). Of course, this code crashes.

GCC is C++ mode silent about it as well.

Let’s try non-optimizing MSVC 2015 x86. It warns about the problem:

```
c:\tmp\3.c(19) : warning C4716: 'create_color': must return a value
```

And generates crashing code:

```
_rt$ = -4
_R$ = 8
_G$ = 12
_B$ = 16
_create_color PROC
    push ebp
    mov ebp, esp
    push ecx
    push 12
    call _malloc
    ; EAX -> ptr to buffer
    add esp, 4
    mov DWORD PTR _rt$[ebp], eax
    mov eax, DWORD PTR _rt$[ebp]
    mov ecx, DWORD PTR _R$[ebp]
    mov DWORD PTR [eax], ecx
    mov edx, DWORD PTR _rt$[ebp]
    mov eax, DWORD PTR _G$[ebp]
    ; EAX is set to G argument:
    mov DWORD PTR [edx+4], eax
    mov ecx, DWORD PTR _rt$[ebp]
    mov edx, DWORD PTR _B$[ebp]
    mov DWORD PTR [ecx+8], edx
    mov esp, ebp
    pop ebp
    ; EAX = G at this point:
    ret 0
_create_color ENDP
```

Now optimizing MSVC 2015 x86 generates crashing code as well, but for the different reason:

```
a$ = -4
main PROC
```
; this is inlined optimized version of create_color():
push    ecx
push    12
call    _malloc
mov     DWORD PTR [eax], 1
mov     DWORD PTR [eax+4], 2
mov     DWORD PTR [eax+8], 3

; EAX -> to allocated buffer, and it's filled, OK
; now we reload ptr to buffer, thinking it's in "a" variable
; but inlined function didn't store pointer to "a" variable!
mov     eax, DWORD PTR _a$[esp+8]

; EAX = some random garbage at this point
push    DWORD PTR [eax+8]
push    DWORD PTR [eax+4]
push    DWORD PTR [eax]
push    OFFSET $SG6074
call    _printf
xor     eax, eax
add     esp, 24
ret 0

_main
ENDP

_R$ = 8
_G$ = 12
_B$ = 16

create_color PROC
push    12
call    _malloc
mov     ecx, DWORD PTR _R$[esp]
add     esp, 4
mov     DWORD PTR [eax], ecx
mov     ecx, DWORD PTR _G$[esp-4]
mov     DWORD PTR [eax+4], ecx
mov     ecx, DWORD PTR _B$[esp-4]
mov     DWORD PTR [eax+8], ecx

; EAX -> to allocated buffer, OK
ret 0

_create_color ENDP

However, non-optimizing MSVC 2015 x64 generates working code:

Listing 3.135: Non-optimizing MSVC 2015 x64

rt$ = 32
R$ = 64
G$ = 72
_B$ = 80

create_color PROC
mov     DWORD PTR [rsp+24], r8d
mov     DWORD PTR [rsp+16], edx
mov     DWORD PTR [rsp+8], ecx
sub     rsp, 56
mov     ecx, 12
call    malloc

; RAX = allocated buffer
mov     QWORD PTR rt$[rsp], rax
mov     rax, QWORD PTR rt$[rsp]
mov     ecx, DWORD PTR R$[rsp]
mov     DWORD PTR [rax], ecx
mov     rax, QWORD PTR rt$[rsp]
mov     ecx, DWORD PTR G$[rsp]
mov     DWORD PTR [rax+4], ecx
mov     rax, QWORD PTR rt$[rsp]
mov     ecx, DWORD PTR B$[rsp]
mov     DWORD PTR [rax+8], ecx
add     rsp, 56

; RAX didn't change down to this point
ret 0

create_color ENDP

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Optimizing MSVC 2015 x64 also inlines the function, as in case of x86, and the resulting code also crashes.

This is a real piece of code from my octothorpe library\(^{66}\), that worked and all tests passed. It was so, without return for quite a time...

```c
uint32_t LPHM_u32_hash(void *key)
{
    jenkins_one_at_a_time_hash_u32((uint32_t)key);
}
```

The moral of the story: warnings are very important, use `-Wall`, etc, etc... When return statement is absent, compiler can just silently do nothing at that point.

Such a bug left unnoticed can ruin a day.

Also, shotgun debugging\(^{67}\) is bad, because again, such a bug can left unnoticed ("everything works now, so be it").

### 3.30 Homework: more about function pointers and unions

This code was copypasted from dwm\(^{68}\), probably, the smallest ever Linux window manager.

The problem: keystrokes from user must be dispatched to various functions inside of dwm. This is usually solved using a big `switch()`. Supposedly, dwm’s creators wanted to make the code neat and modifiable by users:

```c
... 
typedef union {
    int i;
    unsigned int ui;
    float f;
    const void *v;
} Arg;
...

typedef struct {
    unsigned int mod;
    KeySym keysym;
    void (*func)(const Arg *);
    const Arg arg;
} Key;
...

static Key keys[] = {
    /* modifier */
    { MODKEY, XK_p, spawn, {.v = dmenucmd } },
    { MODKEY|ShiftMask, XK_Return, spawn, {.v = termcmd } },
    { MODKEY, XK_b, togglebar, {0} },
    { MODKEY, XK_j, focusstack, {.i = +1 } },
    { MODKEY, XK_k, focusstack, {.i = -1 } },
    { MODKEY, XK_i, incnmaster, {.i = +1 } },
    { MODKEY, XK_d, incnmaster, {.i = -1 } },
    { MODKEY, XK_h, setmfact, {.f = -0.05} },
    { MODKEY, XK_l, setmfact, {.f = +0.05} },
    { MODKEY, XK_T, zoom, {0} },
    { MODKEY, XK_Tab, view, {0} },
    { MODKEY|ShiftMask, XK_c, killclient, {0} },
    { MODKEY, XK_t, setlayout, {.v = &layouts[0]} },
    { MODKEY, XK_f, setlayout, {.v = &layouts[1]} },
}
```

\(^{66}\)https://github.com/DennisYurichev/octothorpe
\(^{67}\)https://en.wikipedia.org/wiki/Shotgun_debugging
\(^{68}\)https://dwm.suckless.org/

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
{ MODKEY, XK_m, setlayout, {v = &layouts[2]} },

... void spawn(const Arg *arg) {
...
void focusstack(const Arg *arg) {
...

For each keystroke (or shortcut) a function is defined. Even more: a parameters (or arguments) to be passed to a function at each case. But parameters can have various type. So union is used here. A value of needed type is filled in the table. Each function takes what it needs.

As a homework, try to write a code like that, or get into dwm's and see how union is passed into functions and handled.

### 3.31 Windows 16-bit

16-bit Windows programs are rare nowadays, but can be used in the cases of retrocomputing or dongle hacking ([8.5 on page 815](#)).

16-bit Windows versions were up to 3.11. 95/98/ME also support 16-bit code, as well as the 32-bit versions of the Windows NT line. The 64-bit versions of Windows NT line do not support 16-bit executable code at all.

The code resembles MS-DOS's one.

Executable files are of type NE-type (so-called “new executable”).

All examples considered here were compiled by the OpenWatcom 1.9 compiler, using these switches:

```bash
wcl.exe -i=C:/WATCOM/h/win/ -s -os -bt=windows -bcl=windows example.c
```

#### 3.31.1 Example#1

```c
#include <windows.h>

int PASCAL WinMain( HINSTANCE hInstance,
    HINSTANCE hPrevInstance,
    LPSTR lpCmdLine,
    int nCmdShow )
{
    MessageBeep(MB_ICONEXCLAMATION);
    return 0;
};
```

```
WinMain proc near
    push    bp
    mov     bp, sp
    mov     ax, 30h ; '0' ; MB_ICONEXCLAMATION constant
    push    ax
    call    MESSAGEBEEP
    xor     ax, ax ; return 0
    pop     bp
    retn    0Ah
WinMain endp
```

Seems to be easy, so far.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
3.31.2 Example #2

```c
#include <windows.h>

int PASCAL WinMain( HINSTANCE hInstance,
                     HINSTANCE hPrevInstance,
                     LPSTR lpCmdLine,
                     int nCmdShow )
{
    MessageBox (NULL, "hello, world", "caption", MB_YESNOCANCEL);
    return 0;
};
```

```asm
WinMain proc near
    push bp
    mov bp, sp
    xor ax, ax          ; NULL
    push ax
    push ds
    mov ax, offset aHelloWorld ; 0x18. "hello, world"
    push ax
    push ds
    mov ax, offset aCaption  ; 0x10. "caption"
    push ax
    mov ax, 3            ; MB_YESNOCANCEL
    push ax
    call MESSAGEBOX
    xor ax, ax            ; return 0
    pop bp
    ret 0
WinMain endp
```

dseg02:0010 aCaption      db 'caption',0

dseg02:0018 aHelloWorld   db 'hello, world',0

Couple important things here: the PASCAL calling convention dictates passing the first argument first (MB_YESNOCANCEL), and the last argument—last (NULL). This convention also tells the callee to restore the stack pointer: hence the RETN instruction has 0Ah as argument, which implies that the pointer has to be increased by 10 bytes when the function exits. It is like stdcall (6.1.2 on page 733), but the arguments are passed in “natural” order.

The pointers are passed in pairs: first the data segment is passed, then the pointer inside the segment. There is only one segment in this example, so DS always points to the data segment of the executable.

3.31.3 Example #3

```c
#include <windows.h>

int PASCAL WinMain( HINSTANCE hInstance,
                     HINSTANCE hPrevInstance,
                     LPSTR lpCmdLine,
                     int nCmdShow )
{
    int result=MessageBox (NULL, "hello, world", "caption", MB_YESNOCANCEL);

    if (result==IDCANCEL)
        MessageBox (NULL, "you pressed cancel", "caption", MB_OK);
    else if (result==IDYES)
        MessageBox (NULL, "you pressed yes", "caption", MB_OK);
    else if (result==IDNO)
        MessageBox (NULL, "you pressed no", "caption", MB_OK);
    return 0;
};
```

WinMain proc near
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Somewhat extended example from the previous section.

### 3.31.4 Example #4

```c
#include <windows.h>

int PASCAL func1 (int a, int b, int c)
{
    return a*b+c;
};

long PASCAL func2 (long a, long b, long c)
{
    return a*b+c;
};

long PASCAL func3 (long a, long b, long c, int d)
{
    return a*b+c-d;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
int PASCAL WinMain( HINSTANCE hInstance,
    HINSTANCE hPrevInstance,
    LPSTR lpCmdLine,
    int nCmdShow )
{
    func1 (123, 456, 789);
    func2 (600000, 700000, 800000);
    func3 (600000, 700000, 800000, 123);
    return 0;
};

func1 proc near
    c = word ptr 4
    b = word ptr 6
    a = word ptr 8

    push   bp
    mov    bp, sp
    mov    ax, [bp+a]
    imul   [bp+b]
    add    ax, [bp+c]
    pop    bp
    retn   6

func1 endp

func2 proc near
    arg_0 = word ptr 4
    arg_2 = word ptr 6
    arg_4 = word ptr 8
    arg_6 = word ptr 0Ah
    arg_8 = word ptr 0Ch
    arg_A = word ptr 0Eh

    push   bp
    mov    bp, sp
    mov    ax, [bp+arg_8]
    mov    dx, [bp+arg_A]
    mov    bx, [bp+arg_4]
    mov    cx, [bp+arg_6]
    call   sub_B2 ; long 32-bit multiplication
    add    ax, [bp+arg_0]
    adc    dx, [bp+arg_2]
    pop    bp
    retn   12

func2 endp

func3 proc near
    arg_0 = word ptr 4
    arg_2 = word ptr 6
    arg_4 = word ptr 8
    arg_6 = word ptr 0Ah
    arg_8 = word ptr 0Ch
    arg_A = word ptr 0Eh
    arg_C = word ptr 10h

    push   bp
    mov    bp, sp
    mov    ax, [bp+arg_A]
    mov    dx, [bp+arg_C]
    mov    bx, [bp+arg_6]
    mov    cx, [bp+arg_8]
    call   sub_B2 ; long 32-bit multiplication
    mov    cx, [bp+arg_2]
    add    cx, ax
    mov    bx, [bp+arg_4]
32-bit values (the long data type implies 32 bits, while int is 16-bit) in 16-bit code (both MS-DOS and Win16) are passed in pairs. It is just like when 64-bit values are used in a 32-bit environment (1.34 on page 398).

sub_B2 here is a library function written by the compiler’s developers that does “long multiplication”, i.e., multiplies two 32-bit values. Other compiler functions that do the same are listed here: .5 on page 1016, .4 on page 1016.

The ADD/ADC instruction pair is used for addition of compound values: ADD may set/clear the CF flag, and ADC uses it after.

The SUB/SBB instruction pair is used for subtraction: SUB may set/clear the CF flag, SBB uses it after.

32-bit values are returned from functions in the DX:AX register pair.

Constants are also passed in pairs in WinMain() here.
The int-typed 123 constant is first converted according to its sign into a 32-bit value using the CWD instruction.

### 3.31.5 Example #5

```pascal
#include <windows.h>

int PASCAL string_compare (char *s1, char *s2)
{
    while (1)
    {
        if (*s1=*s2)
            return 0;
        if (*s1==0 || *s2==0)
            return 1; // end of string
        s1++; s2++;
    }
}

int PASCAL string_compare_far (char far *s1, char far *s2)
{
    while (1)
    {
        if (*s1=*s2)
            return 0;
        if (*s1==0 || *s2==0)
            return 1; // end of string
        s1++; s2++;
    }
}

void PASCAL remove_digits (char *s)
{
    while (*s)
    {
        if (*s>='0' && *s<='9')
            *s='-';
        s++;
    }
}

char str[]="hello 1234 world";

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Here we see a difference between the so-called “near” pointers and the “far” pointers: another weird artifact of segmented memory in 16-bit 8086.

You can read more about it here: 11.6 on page 976.

“near” pointers are those which point within the current data segment. Hence, the string_compare() function takes only two 16-bit pointers, and accesses the data from the segment that DS points to (The mov al, [bx] instruction actually works like mov al, ds:[bx] — DS is implicit here).

“far” pointers are those which may point to data in another memory segment. Hence string_compare_far() takes the 16-bit pair as a pointer, loads the high part of it in the ES segment register and accesses the data through it (mov al, es:[bx]). “far” pointers are also used in my MessageBox() win16 example: 3.31.2 on page 650. Indeed, the Windows kernel is not aware which data segment to use when accessing text strings, so it need the complete information.

The reason for this distinction is that a compact program may use just one 64kb data segment, so it doesn’t need to pass the high part of the address, which is always the same. A bigger program may use several 64kb data segments, so it needs to specify the segment of the data each time.

It’s the same story for code segments. A compact program may have all executable code within one 64kb-segment, then all functions in it will be called using the CALL NEAR instruction, and the code flow will be returned using RETN. But if there are several code segments, then the address of the function is to be specified by a pair, it is to be called using the CALL FAR instruction, and the code flow is to be returned using RETF.

This is what is set in the compiler by specifying “memory model”.

The compilers targeting MS-DOS and Win16 have specific libraries for each memory model: they differ by pointer types for code and data.

### 3.31.6 Example #6

```c
#include <windows.h>
#include <time.h>
#include <stdio.h>

char strbuf[256];

int PASCAL WinMain( HINSTANCE hInstance,
                    HINSTANCE hPrevInstance,
                    LPSTR lpCmdLine,
                    int nCmdShow )
{
    struct tm *t;
    time_t unix_time;

    unix_time=time(NULL);
    t=localtime (&unix_time);

    sprintf (strbuf, "%04d-%02d-%02d %02d:%02d:%02d",
             t->tm_year+1900, t->tm_mon,
             t->tm_mday, t->tm_hour,
             t->tm_min, t->tm_sec);

    MessageBox (NULL, strbuf, "caption", MB_OK);
    return 0;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
UNIX time is a 32-bit value, so it is returned in the DX:AX register pair and stored in two local 16-bit variables. Then a pointer to the pair is passed to the localtime() function. The localtime() function has a struct tm allocated somewhere in the guts of the C library, so only a pointer to it is returned.

By the way, this also implies that the function cannot be called again until its results are used.

For the time() and localtime() functions, a Watcom calling convention is used here: the first four arguments are passed in the AX, DX, BX and CX, registers, and the rest arguments are via the stack.

The functions using this convention are also marked by underscore at the end of their name.

sprintf() does not use the PASCAL calling convention, nor the Watcom one, so the arguments are passed in the normal cdecl way (6.1.1 on page 733).

Global variables

This is the same example, but now these variables are global:

```c
#include <windows.h>
#include <time.h>
#include <stdio.h>

char strbuf[256];
struct tm *t;
time_t unix_time;
```
int PASCAL WinMain( HINSTANCE hInstance,
                  HINSTANCE hPrevInstance,
                  LPSTR lpCmdLine,
                  int nCmdShow )
{
    unix_time=time(NULL);
    t=localtime (&unix_time);
    sprintf (strbuf, "%04d-%02d-%02d %02d:%02d:%02d", t->tm_year+1900, t->tm_mon, t->tm_mday,
             t->tm_hour, t->tm_min, t->tm_sec);
    MessageBox (NULL, strbuf, "caption", MB_OK);
    return 0;
};

unix_time_low  dw 0
unix_time_high dw 0
t         dw 0

WinMain proc near
push bp
mov bp, sp
xor ax, ax
call time_
mov unix_time_low, ax
mov unix_time_high, dx
mov ax, offset unix_time_low
call localtime_
mov bx, ax
mov t, ax ; will not be used in future...
push word ptr [bx] ; seconds
push word ptr [bx+2] ; minutes
push word ptr [bx+4] ; hour
push word ptr [bx+6] ; day
push word ptr [bx+8] ; month
mov ax, [bx+0Ah] ; year
add ax, 1900
push ax
mov ax, offset a04d02d02d02d02d ; "%04d-%02d-%02d %02d:%02d:%02d"
push ax
mov ax, offset strbuf
push ax
call sprintf_
add sp, 10h
xor ax, ax ; NULL
push ax
push ds
mov ax, offset strbuf
push ax
push ds
mov ax, offset acaption ; "caption"
push ax
xor ax, ax ; MB_OK
push ax
call MESSAGEBOX
xor ax, ax ; return 0
pop bp
retn 0Ah

WinMain endp

t is not to be used, but the compiler emitted the code which stores the value.
Because it is not sure, maybe that value will eventually be used in some other module.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Chapter 4

Java

4.1 Java

4.1.1 Introduction

There are some well-known decompilers for Java (or JVM bytecode in general)\(^1\). The reason is the decompilation of JVM-bytecode is somewhat easier than for lower level x86 code:

- There is much more information about the data types.
- The JVM memory model is much more rigorous and outlined.
- The Java compiler don’t do any optimizations (the JVM JIT\(^2\) does them at runtime), so the bytecode in the class files is usually pretty readable.

When can the knowledge of JVM be useful?

- Quick-and-dirty patching tasks of class files without the need to recompile the decompiler’s results.
- Analyzing obfuscated code.
- Building your own obfuscator.
- Building a compiler codegenerator (back-end) targeting JVM (like Scala, Clojure, etc.\(^3\)).

Let’s start with some simple pieces of code. JDK 1.7 is used everywhere, unless mentioned otherwise.

This is the command used to decompile class files everywhere:

```
javap -c -verbose
```

This is the book I used while preparing all examples: [Tim Lindholm, Frank Yellin, Gilad Bracha, Alex Buckley, *The Java(R) Virtual Machine Specification / Java SE 7 Edition*]\(^4\).

4.1.2 Returning a value

Probably the simplest Java function is the one which returns some value.

Oh, and we must keep in mind that there are no “free” functions in Java in common sense, they are “methods”.

Each method is related to some class, so it’s not possible to define a method outside of a class.

But we’ll call them “functions” anyway, for simplicity.

```
public class ret
{
    public static int main(String[] args)
    {
        return 0;
    }
}
```

\(^1\)For example, JAD: http://varaneckas.com/jad/

\(^2\)Just-In-Time compilation

\(^3\)Full list: http://en.wikipedia.org/wiki/List_of_JVM_languages

\(^4\)Also available as https://docs.oracle.com/javase/specs/jvms/se7/jvms7.pdf; http://docs.oracle.com/javase/specs/jvms/se7/html/
Let's compile it:

```bash
javac ret.java
```

...and decompile it using the standard Java utility:

```bash
javap -c -verbose ret.class
```

And we get:

Listing 4.1: JDK 1.7 (excerpt)

```java
public static int main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
  stack=1, locals=1, args_size=1
  0: iconst_0
  1: ireturn
```

The Java developers decided that 0 is one of the busiest constants in programming, so there is a separate short one-byte `iconst_0` instruction which pushes 0.

5. There are also `iconst_1` (which pushes 1), `iconst_2`, etc., up to `iconst_5`. There is also `iconst_m1` which pushes -1.

The stack is used in JVM for passing data to called functions and also for return values. So `iconst_0` pushes 0 into the stack. `ireturn` returns an integer value (`i` in name means integer) from the TOS.

Let's rewrite our example slightly, now we return 1234:

```java
public class ret {
    public static int main(String[] args) {
        return 1234;
    }
}
```

...we get:

Listing 4.2: JDK 1.7 (excerpt)

```java
public static int main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
  stack=1, locals=1, args_size=1
  0: sipush 1234
  3: ireturn
```

`sipush` (short `integer`) pushes 1234 into the stack. `short` in name implies a 16-bit value is to be pushed. The number 1234 indeed fits well in a 16-bit value.

What about larger values?

```java
public class ret {
    public static int main(String[] args) {
        return 12345678;
    }
}
```

6. Just like in MIPS, where a separate register for zero constant exists: 1.5.4 on page 25.

Top of Stack

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
It’s not possible to encode a 32-bit number in a JVM instruction opcode, the developers didn’t leave such possibility.

So the 32-bit number 12345678 is stored in so called “constant pool” which is, let’s say, the library of most used constants (including strings, objects, etc.).

This way of passing constants is not unique to JVM.

MIPS, ARM and other RISC CPUs also can’t encode a 32-bit number in a 32-bit opcode, so the RISC CPU code (including MIPS and ARM) has to construct the value in several steps, or to keep it in the data segment: 1.39.3 on page 445, 1.40.1 on page 448.

MIPS code also traditionally has a constant pool, named “literal pool”, the segments are called “.lit4” (for 32-bit single precision floating point number constants) and “.lit8” (for 64-bit double precision floating point number constants).

Let’s try some other data types!

Boolean:

```java
public class ret {
    public static boolean main(String[] args) {
        return true;
    }
}
```

This JVM bytecode is no different from one returning integer 1.

32-bit data slots in the stack are also used here for boolean values, like in C/C++. But one could not use returned boolean value as integer or vice versa — type information is stored in the class file and checked at runtime.

It’s the same story with a 16-bit short:

```java
public class ret {
    public static short main(String[] args) {
        return 1234;
    }
}
```
...and char!

```java
public class ret {
    public static char main(String[] args) {
        return 'A';
    }
}
```

```java
public static char main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=1, locals=1, args_size=1
    0: bipush 65
    2: ireturn
```

bipush means “push byte”. Needless to say that a char in Java is 16-bit UTF-16 character, and it’s equivalent to short, but the ASCII code of the “A” character is 65, and it’s possible to use the instruction for pushing a byte in the stack.

Let’s also try a byte:

```java
public class retc {
    public static byte main(String[] args) {
        return 123;
    }
}
```

```java
public static byte main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=1, locals=1, args_size=1
    0: bipush 123
    2: ireturn
```

One may ask, why bother with a 16-bit short data type which internally works as a 32-bit integer? Why use a char data type if it is the same as a short data type?
The answer is simple: for data type control and source code readability.
A char may essentially be the same as a short, but we quickly grasp that it’s a placeholder for an UTF-16 character, and not for some other integer value.
When using short, we show everyone that the variable’s range is limited by 16 bits.
It’s a very good idea to use the boolean type where needed to, instead of the C-style int.
There is also a 64-bit integer data type in Java:

```java
public class ret3 {
    public static long main(String[] args) {
        return 1234567890123456789L;
    }
}
```

Listing 4.4: Constant pool

```java
... #2 = Long 1234567890123456789l ...
```

```java
public static long main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=1, args_size=1
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The 64-bit number is also stored in a constant pool, `ldc2_w` loads it and `lreturn` (long return) returns it. The `ldc2_w` instruction is also used to load double precision floating point numbers (which also occupy 64 bits) from a constant pool:

```
public class ret {
    public static double main(String[] args) {
        return 123.456d;
    }
}
```

Listing 4.5: Constant pool

```
... #2 = Double 123.456d ...
```

`dreturn` stands for “return double”. And finally, a single precision floating point number:

```
public class ret {
    public static float main(String[] args) {
        return 123.456f;
    }
}
```

Listing 4.6: Constant pool

```
... #2 = Float 123.456f ...
```

The `ldc` instruction used here is the same one as for loading 32-bit integer numbers from a constant pool. `freturn` stands for “return float”.

Now what about function that return nothing?

```
public class ret {
    public static void main(String[] args) {
        return;
    }
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This means that the return instruction is used to return control without returning an actual value. Knowing all this, it’s very easy to deduce the function’s (or method’s) returning type from the last instruction.

### 4.1.3 Simple calculating functions

Let's continue with a simple calculating functions.

```java
public class calc {
    public static int half(int a) {
        return a/2;
    }
}
```

Here’s the output when the `iconst_2` instruction is used:

```java
public static int half(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=1, args_size=1
0: iload_0
1: iconst_2
2: idiv
3: ireturn
```

`iload_0` takes the zeroth function argument and pushes it to the stack. `iconst_2` pushes 2 in the stack. After the execution of these two instructions, this is how stack looks like:

```
+--------+
| result |
+--------+
```

`idiv` just takes the two values at the TOS, divides one by the other and leaves the result at TOS:

```
TOS ->| result |
```

`ireturn` takes it and returns.

Let’s proceed with double precision floating point numbers:

```java
public class calc {
    public static double half_double(double a) {
        return a/2.0;
    }
}
```

Listing 4.7: Constant pool

```
... #2 = Double 2.0d ...
...  ```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
public static double half_double(double);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=4, locals=2, args_size=1
    0: dload_0
    1: ldc2_w  #2       // double 2.0d
    4: ddiv
    5: dreturn

It’s the same, but the ldc2_w instruction is used to load the constant 2.0 from the constant pool.
Also, the other three instructions have the d prefix, meaning they work with double data type values.
Let’s now use a function with two arguments:

public class calc
{
    public static int sum(int a, int b)
    {
        return a+b;
    }
}

public static int sum(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=2, args_size=2
    0: iload_0
    1: iload_1
    2: iadd
    3: ireturn

iload_0 loads the first function argument (a), iload_1—second (b).
Here is the stack after the execution of both instructions:

+---+
| b |  
+---+
| a |  
+---+

iadd adds the two values and leaves the result at TOS:

+-----------+
| result |  
+-----------+

Let’s extend this example to the long data type:

public static long lsum(long a, long b)
{
    return a+b;
}

...we got:

public static long lsum(long, long);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=4, locals=4, args_size=2
    0: lload_0
    1: lload_2
    2: ladd
    3: lreturn

The second lload instruction takes the second argument from the 2nd slot.
That’s because a 64-bit long value occupies exactly two 32-bit slots.
Slightly more advanced example:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
public class calc {
    public static int mult_add(int a, int b, int c) {
        return a*b+c;
    }
}

public static int mult_add(int, int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=3, args_size=3
0: iload_0
1: iload_1
2: imul
3: iload_2
4: iadd
5: ireturn

The first step is multiplication. The product is left at the TOS:

TOS ->| product |
       +--------+

iload_2 loads the third argument (c) in the stack:

TOS ->| c       |
       +--------+
| product |
       +--------+

Now the iadd instruction can add the two values.

4.1.4 JVM memory model

x86 and other low-level environments use the stack for argument passing and as a local variables storage. JVM is slightly different.

It has:

- Local variable array (LVA\(^7\)). Used as storage for incoming function arguments and local variables. Instructions like iload_0 load values from it. istore stores values in it. At the beginning the function arguments are stored: starting at 0 or at 1 (if the zeroth argument is occupied by this pointer).

Then the local variables are allocated. Each slot has size of 32-bit.

Hence, values of long and double data types occupy two slots.

- Operand stack (or just “stack”). It’s used for computations and passing arguments while calling other functions.

Unlike low-level environments like x86, it’s not possible to access the stack without using instructions which explicitly pushes or pops values to/from it.

- Heap. It is used as storage for objects and arrays.

These 3 areas are isolated from each other.

\(^7\)(Java) Local Variable Array

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
4.1.5 Simple function calling

Math.random() returns a pseudorandom number in range of [0.0 ...1.0), but let’s say that for some reason we need to devise a function that returns a number in range of [0.0 ...0.5):

```java
public class HalfRandom {
    public static double f() {
        return Math.random() / 2;
    }
}
```

Listing 4.8: Constant pool

```
... #2 = Methodref #18.#19 // java/lang/Math.random():D
#3 = Double 2.0d
...
#12 = Utf8 ()D
...
#18 = Class #22 // java/lang/Math
#19 = NameAndType #23:#12 // random():D
#22 = Utf8 java/lang/Math
#23 = Utf8 random
```

invokestatic calls the Math.random() function and leaves the result at the TOS. Then the result is divided by 2.0 and returned.

But how is the function name encoded?

It’s encoded in the constant pool using a Methodref expression.

It defines the class and method names. The first field of Methodref points to a Class expression which, in turn, points to the usual text string (“java/lang/Math”).

The second Methodref expression points to a NameAndType expression which also has two links to the strings.

The first string is “random”, which is the name of the method.

The second string is “()D”, which encodes the function’s type. It means that it returns a double value (hence the D in the string).

This is the way 1) JVM can check data for type correctness; 2) Java decompilers can restore data types from a compiled class file.

Now let’s try the “Hello, world!” example:

```java
public class HelloWorld {
    public static void main(String[] args) {
        System.out.println("Hello, World");
    }
}
```

Listing 4.9: Constant pool

```
public static double f();
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=4, locals=0, args_size=0
    0: invokestatic #2 // Method java/lang/Math.random():D
    3: ldc2_w #3 // double 2.0d
    6: ddiv
    7: dreturn
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
4.1.6 Calling beep()

This is a simple calling of two functions without arguments:

```java
public static void main(String[] args)
{
    java.awt.Toolkit.getDefaultToolkit().beep();
}
```

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=1, locals=1, args_size=1
  0: invokestatic #2 // Method java/awt/Toolkit.getDefaultToolkit():Ljava/awt/Toolkit;
  5: return
```

About difference in pointers and reference's in C++ see: 3.19.3 on page 565.
First invokevirtual at offset 0 calls java.awt.Toolkit.getDefaultToolkit(), which returns a reference to an object of class Toolkit. The invokevirtual instruction at offset 3 calls the beep() method of this class.

### 4.1.7 Linear congruential PRNG

Let's try a simple pseudorandom numbers generator, which we already considered once in the book (1.29 on page 341):

```java
public class LCG {
    public static int rand_state;
    public void my_srand(int init) {
        rand_state = init;
    }
    public static int RNG_a = 1664525;
    public static int RNG_c = 1013904223;
    public int my_rand() {
        rand_state = rand_state * RNG_a;
        rand_state = rand_state + RNG_c;
        return rand_state & 0x7fff;
    }
}
```

There are couple of class fields which are initialized at start. But how? In javap output we can find the class constructor:

```java
static {};
flags: ACC_STATIC
Code:
    stack=1, locals=0, args_size=0
0: ldc #5 // int 1664525
2: putstatic #3 // Field RNG_a:I
5: ldc #6 // int 1013904223
7: putstatic #4 // Field RNG_c:I
10: return
```

That's the way variables are initialized. RNG_a occupies the 3rd slot in the class and RNG_c—4th, and putstatic puts the constants there. The my_srand() function just stores the input value in rand_state:

```java
public void my_srand(int); flags: ACC_PUBLIC
Code:
    stack=1, locals=2, args_size=2
0: iload_1
1: putstatic #2 // Field rand_state:I
4: return
```

Iload_1 takes the input value and pushes it into stack. But why not iload_0? It's because this function may use fields of the class, and so this is also passed to the function as a zeroth argument.

The field rand_state occupies the 2nd slot in the class, so putstatic copies the value from the TOS into the 2nd slot.

Now my_rand():

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
public int my_rand();
flags: ACC_PUBLIC
Code:
    stack=2, locals=1, args_size=1
    0: getstatic  #2 // Field rand_state:I
    3: getstatic  #3 // Field RNG_a:I
    6: imul
    7: putstatic #2 // Field rand_state:I
    10: getstatic #2 // Field rand_state:I
    13: getstatic #4 // Field RNG_c:I
    16: iadd
    17: putstatic #2 // Field rand_state:I
    20: getstatic #2 // Field rand_state:I
    23: sipush 32767
    26: iand
    27: ireturn
It just loads all the values from the object’s fields, does the operations and updates rand_state’s value using the putstatic instruction.

At offset 20, rand_state is reloaded again (because it has been dropped from the stack before, by putstatic).

This looks like non-efficient code, but be sure, the JVM is usually good enough to optimize such things really well.

4.1.8  Conditional jumps

Now let’s proceed to conditional jumps.

public class abs
{
    public static int abs(int a)
    {
        if (a<0)
            return -a;
        return a;
    }
}

public static int abs(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=1, locals=1, args_size=1
    0: iload_0
    1: ifge 7
    4: iload_0
    5: ineg
    6: ireturn
    7: iload_0
    8: ireturn
ifge jumps to offset 7 if the value at TOS is greater or equal to 0.

Don’t forget, any ifXX instruction pops the value (to be compared) from the stack.

ineg just negates value at TOS.

Another example:

    public static int min (int a, int b)
    {
        if (a>b)
            return b;
        return a;
    }

We get:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
public static int min(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=2, args_size=2
  0: iload_0
  1: iload_1
  2: if_icmple 7
  5: iload_1
  6: ireturn
  7: iload_0
  8: ireturn

if_icmple pops two values and compares them. If the second one is lesser than (or equal to) the first, a
jump to offset 7 is performed.

When we define max() function ...

public static int max (int a, int b)
{
    if (a>b)
        return a;
    return b;
}

...the resulting code is the same, but the last two iload instructions (at offsets 5 and 7) are swapped:

A more advanced example:

public class cond
{
    public static void f(int i)
    {
        if (i<100)
            System.out.print("<100");
        if (i==100)
            System.out.print("==100");
        if (i>100)
            System.out.print(">100");
        if (i==0)
            System.out.print("==0");
    }
}

public static void f(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=1, args_size=1
  0: iload_0
  1: bipush 100
  3: if_icmpge 14
  6: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
  9: ldc #3 // String <100
 11: invokevirtual #4 // Method java/io/PrintStream.print:(Ljava/lang/String;)V
14: iload_0
15: bipush 100
17: if_icmpne 28
20: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
if_icmpge pops two values and compares them. If the second one is larger than the first, a jump to offset 14 is performed.

if_icmpne and if_icmple work just the same, but implement different conditions.

There is also a ifne instruction at offset 43.

Its name is misnomer, it would’ve be better to name it ifnz (jump if the value at TOS is not zero).

And that is what it does: it jumps to offset 54 if the input value is not zero.

If zero, the execution flow proceeds to offset 46, where the “==0” string is printed.

N.B.: JVM has no unsigned data types, so the comparison instructions operate only on signed integer values.

### 4.1.9 Passing arguments

Let’s extend our min()/max() example:

```java
class minmax {
    public static int min (int a, int b) {
        if (a>b)
            return b;
        return a;
    }
    public static int max (int a, int b) {
        if (a>b)
            return a;
        return b;
    }
    public static void main(String[] args) {
        int a=123, b=456;
        int max_value=max(a, b);
        int min_value=min(a, b);
        System.out.println(min_value);
        System.out.println(max_value);
    }
}
```

Here is main() function code:

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=5, args_size=1
  0: bipush 123
  2: istore 1
  3: sipush 456
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Arguments are passed to the other function in the stack, and the return value is left on TOS.

4.1.10 Bitfields

All bit-wise operations work just like in any other ISA:

```java
public static int set(int a, int b) {
    return a | 1<<b;
}

public static int clear(int a, int b) {
    return a & (~(1<<b));
}
```

iconst_m1 loads −1 in the stack, it’s the same as the 0xFFFFFFFF number.

XORing with 0xFFFFFFFF has the same effect of inverting all bits (2.6 on page 466).

Let's extend all data types to 64-bit long:

```java
public static long lset (long a, int b) {
    return a | 1<<b;
}
```
public static long lclear (long a, int b) {
    return a & -(1<<b));
}

public static long lset(long, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=4, locals=3, args_size=2
0: lload_0
1: iconst_1
2: iload_2
3: ishl
4: i2l
5: lor
6: lreturn

The code is the same, but instructions with l prefix are used, which operate on 64-bit values.
Also, the second argument of the function still is of type int, and when the 32-bit value in it needs to be promoted to 64-bit value the i2l instruction is used, which essentially extend the value of an integer type to a long one.

4.1.11 Loops

public class Loop {
    public static void main(String[] args) {
        for (int i = 1; i <= 10; i++) {
            System.out.println(i);
        }
    }
}

public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=2, args_size=1
0: iconst_1
1: istore_1
2: iload_1
3: bipush 10
5: if_icmpgt 21
8: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
11: iload_1
12: invokevirtual #3 // Method java/io/PrintStream.println:(I)V
15: iinc 1, 1
18: goto 2
21: return

iconst_1 loads 1 into TOS, istore_1 stores it in the LVA at slot 1.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Why not the zeroth slot? Because the `main()` function has one argument (array of `String`) and a pointer to it (or reference) is now in the zeroth slot.

So, the `i` local variable will always be in 1st slot.

Instructions at offsets 3 and 5 compare `i` with 10.

If `i` is larger, execution flow passes to offset 21, where the function ends.

If it's not, `println` is called.

`i` is then reloaded at offset 11, for `println`.

By the way, we call the `println` method for an integer, and we see this in the comments: “(I)V” (I means integer and V means the return type is void).

When `println` finishes, `i` is incremented at offset 15.

The first operand of the instruction is the number of a slot (1), the second is the number (1) to add to the variable.

goto is just GOTO, it jumps to the beginning of the loop's body offset 2.

Let's proceed with a more complex example:

```java
public class Fibonacci {
    public static void main(String[] args) {
        int limit = 20, f = 0, g = 1;
        for (int i = 1; i <= limit; i++) {
            f = f + g;
            g = f - g;
            System.out.println(f);
        }
    }
}
```

```java
public static void main(java.lang.String[]); flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=5, args_size=1
0: bipush 20
2: istore_1
3: iconst_0
4: istore_2
5: iconst_1
6: istore_3
7: iconst_1
8: istore 4
10: iload 4
12: iload_1
13: if_icmpgt 37
16: iload_2
17: iload_3
18: iadd
19: istore_2
20: iload_2
21: iload_3
22: isub
23: istore_3
24: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
27: iload_2
28: invokevirtual #3 // Method java/io/PrintStream.println:(I)V
31: iinc 4, 1
34: goto 10
37: return
```

Here is a map of the LVA slots:

- 0 — the sole argument of `main()`
• 1 — limit, always contains 20
• 2 — f
• 3 — g
• 4 — i

We can see that the Java compiler allocates variables in LVA slots in the same order they were declared in the source code.

There are separate istore instructions for accessing slots 0, 1, 2 and 3, but not for 4 and larger, so there is istore with an additional operand at offset 8 which takes the slot number as an operand.

It’s the same with iload at offset 10.

But isn’t it dubious to allocate another slot for the limit variable, which always contains 20 (so it’s a constant in essence), and reload its value so often?

JVM JIT compiler is usually good enough to optimize such things.

Manual intervention in the code is probably not worth it.

### 4.1.12 switch()

The switch() statement is implemented with the tableswitch instruction:

```java
class Example {
    public static void f(int a) {
        switch (a) {
            case 0: System.out.println("zero"); break;
            case 1: System.out.println("one
"); break;
            case 2: System.out.println("two
"); break;
            case 3: System.out.println("three
"); break;
            case 4: System.out.println("four
"); break;
            default: System.out.println("something unknown
"); break;
        }
    }
}
```

As simple, as possible:

```java
public static void f(int a) {
    switch (a) {
        case 0: System.out.println("zero"); break;
        case 1: System.out.println("one
"); break;
        case 2: System.out.println("two
"); break;
        case 3: System.out.println("three
"); break;
        case 4: System.out.println("four
"); break;
        default: System.out.println("something unknown
"); break;
    }
}
```

```
    |
0: | iload 0 |
  |
1: | tableswitch { // 0 to 4
  |
0: | 36 |
1: | 47 |
2: | 58 |
3: | 69 |
4: | 80 |
  |
default: 91
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
4.1.13 Arrays

Simple example

Let's first create an array of 10 integers and fill it:

```java
public static void main(String[] args) {
    int[] a = new int[10];
    for (int i = 0; i < 10; i++)
        a[i] = i;
    dump(a);
}
```

The `newarray` instruction creates an array object of 10 `int` elements.
The array’s size is set with `bipush` and left at TOS.
The array’s type is set in `newarray` instruction’s operand.
After `newarray`’s execution, a reference (or pointer) to the newly created array in the heap is left at the TOS.
`astore_1` stores the reference to the 1st slot in LVA.
The second part of the `main()` function is the loop which stores `i` into the corresponding array element.
`aload_1` gets a reference of the array and places it in the stack.
`iastore` then stores the integer value from the stack in the array, reference of which is currently in TOS.
The third part of the `main()` function calls the `dump()` function.
An argument for it is prepared by `aload_1` (offset 23).
Now let’s proceed to the `dump()` function:

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=3, args_size=1
    0: bipush 10
    2: newarray int
    4: astore_1
    5: iconst_0
    6: istore_2
    7: iload_2
    8: bipush 10
   10: if_icmpge 23
   13: aload_1
   14: iload_2
   15: iload_2
   16: iastore
   17: iinc 2, 1
   20: goto 7
   23: aload_1
   24: invokestatic #4 // Method dump:([I)V
   27: return
```
public static void dump(int a[]) {
    for (int i=0; i<a.length; i++)
        System.out.println(a[i]);
}

public static void dump(int[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=2, args_size=1
    0: iconst_0
    1: istore_1
    2: iload_1
    3: aload_0
    4: arraylength
    5: if_icmpge 23
    8: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
    11: aload_0
    12: iload_1
    13: iaload
    14: invokevirtual #3 // Method java/io/PrintStream.println:(I)V
    17: iinc 1, 1
    20: goto 2
    23: return

The incoming reference to the array is in the zeroth slot.
The a.length expression in the source code is converted to an arraylength instruction: it takes a reference to the array and leaves the array size at TOS.
iaload at offset 13 is used to load array elements, it requires to array reference be present in the stack (prepared by aload_0 at 11), and also an index (prepared by iload_1 at offset 12).
Needless to say, instructions prefixed with a may be mistakenly comprehended as array instructions.
It’s not correct. These instructions works with references to objects.
And arrays and strings are objects too.

Summing elements of array

Another example:

public class ArraySum {
    public static int f (int[] a) {
        int sum=0;
        for (int i=0; i<a.length; i++)
            sum=sum+a[i];
        return sum;
    }
}

public static int f(int[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=3, args_size=1
    0: iconst_0
    1: istore_1
    2: iload_0
    3: iload_1
    4: iinc 1, 1
    7: if_icmpge 22
    10: aaload
    11: aaload

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
LVA slot 0 contains a reference to the input array.
LVA slot 1 contains the local variable sum.

The only argument of the main() function is an array too

We’ll be using the only argument of the main() function, which is an array of strings:

```java
class UseArgument {
    public static void main(String[] args) {
        System.out.print("Hi,");
        System.out.print(args[1]);
        System.out.println(" How are you?");
    }
}
```

The zeroth argument is the program’s name (like in C/C++, etc.), so the 1st argument supplied by the user is 1st.

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=1, args_size=1
0: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
3: ldc #3 // String Hi,
5: invokevirtual #4 // Method java/io/PrintStream.print:(Ljava/lang/String;)V
8: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
11: aload_0
12: iconst_1
13: aaload
14: invokevirtual #4 // Method java/io/PrintStream.print:(Ljava/lang/String;)V
17: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
20: ldc #5 // String . How are you?
22: invokevirtual #6 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
25: return
```

aload_0 at 11 loads a reference of the zeroth LVA slot (1st and only main() argument).
iconst_1 and aaload at 12 and 13 take a reference to the first (counting at 0) element of array.
The reference to the string object is at TOS at offset 14, and it is taken from there by println method.

Pre-initialized array of strings

```java
class Month {
    public static String[] months = {
        "January",
        "February",
        "March",
        "April",
        "May",
        "June",
        "July",
        "August",
    }
```
The `get_month()` function is simple: Функция `get_month()` проста:

```java
public String get_month (int i)
{
    return months[i];
}
```

Java String are objects, so the `a`-instructions are used to operate on them.
`areturn` returns a `reference` to a String object.

How is the `months[]` array initialized?

```java
static {}
flags: ACC_STATIC
Code:
stack=4, locals=0, args_size=0
0: bipush 12
  // Field months:[Ljava/lang/String;
2: anewarray #3 // class java/lang/String
5: dup       // Field: months
6: iconst_0
7: ldc #4 // String January
9: aastore
10: dup
11: iconst_1
12: ldc #5 // String February
14: aastore
15: dup
16: iconst_2
17: ldc #6 // String March
19: aastore
20: dup
21: iconst_3
22: ldc #7 // String April
24: aastore
25: dup
26: iconst_4
27: ldc #8 // String May
29: aastore
30: dup
31: iconst_5
32: ldc #9 // String June
34: aastore
35: dup
36: bipush 6
38: ldc #10 // String July
40: aastore
41: dup
42: bipush 7
44: ldc #11 // String August
46: aastore
47: dup
48: bipush 8
```

(For statistics collecting purposes) if you’ve read this far, please click [here](http://example.com). Thanks!
50: ldc #12 // String September
52: aastore
53: dup
54: bipush 9
56: ldc #13 // String October
58: aastore
59: dup
60: bipush 10
62: ldc #14 // String November
64: aastore
65: dup
66: bipush 11
68: ldc #15 // String December
70: aastore
71: putstatic #2 // Field months:[Ljava/lang/String;
74: return

anewarray creates a new array of references (hence a prefix).
The object’s type is defined in the anewarray’s operand, it is the “java/lang/String” string.
The bipush 12 before anewarray sets the array’s size.
We see here a new instruction for us: dup.
It’s a standard instruction in stack computers (including the Forth programming language) which just duplicates the value at TOS.
By the way, FPU 80x87 is also a stack computer and it has similar instruction – FDUP.
It is used here to duplicate a reference to an array, because the aastore instruction pops the reference to array from the stack, but subsequent aastore will need it again.
The Java compiler concluded that it’s better to generate a dup instead of generating a getstatic instruction before each array store operation (i.e., 11 times).
aastore puts a reference (to string) into the array at an index which is taken from TOS.
Finally, putstatic puts reference to the newly created array into the second field of our object, i.e., months field.

Variadic functions

Variadic functions actually use arrays:

```
public static void f(int... values)
{
    for (int i=0; i<values.length; i++)
        System.out.println(values[i]);
}

public static void main(String[] args)
{
    f (1,2,3,4,5);
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
f() just takes an array of integers using `aload_0` at offset 3.

Then it gets the array's size, etc.

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=4, locals=1, args_size=1
0: iconst_5
1: anewarray int
3: dup
4: iconst_0
5: iconst_1
6: iastore
7: dup
8: iconst_1
9: iconst_2
10: iastore
11: dup
12: iconst_2
13: iconst_3
14: iastore
15: dup
16: iconst_3
17: iconst_4
18: iastore
19: dup
20: iconst_4
21: iconst_5
22: iastore
23: invokestatic #4 // Method f:([I)V
26: return
```

The array is constructed in `main()` using the `newarray` instruction, then it's filled, and `f()` is called.

Oh, by the way, array object is not destroyed at the end of `main()`.

There are no destructors in Java at all, because the JVM has a garbage collector which does this automatically, when it feels it needs to.

What about the `format()` method?

It takes two arguments at input: a string and an array of objects:

```java
public PrintStream format(String format, Object... args)
( http://docs.oracle.com/javase/tutorial/java/data/numberformat.html )
```

Let's see:

```java
public static void main(String[] args)
{
int i=123;
double d=123.456;
System.out.format("int: %d double: %f.%n", i, d);
}
```

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=7, locals=4, args_size=1
0: bipush 123
2: istore_1
3: ldc2_w #2 // double 123.456d
6: dstore_2
7: getstatic #4 // Field java/lang/System.out:Ljava/io/PrintStream;
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
10: ldc #5 // String int: %d double: %f.%n
12: iconst_2
13: anewarray #6 // class java/lang/Object
16: dup
17: iconst_0
18: iload_1
19: invokestatic #7 // Method java/lang/Integer.valueOf:(I)Ljava/lang/Integer;
22: aastore
23: dup
24: iconst_1
25: dload_2
29: aastore
30: invokevirtual #9 // Method java/io/PrintStream.format:(Ljava/lang/String;[Ljava/lang/Object;)Ljava/io/PrintStream;
33: pop
34: return

So values of the int and double types are first promoted to Integer and Double objects using the valueOf methods.

The format() method needs objects of type Object at input, and since the Integer and Double classes are derived from the root Object class, they suitable for elements in the input array.

On the other hand, an array is always homogeneous, i.e., it can’t hold elements of different types, which makes it impossible to push int and double values in it.

An array of Object objects is created at offset 13, an Integer object is added to the array at offset 22, and a Double object is added to the array at offset 29.

The penultimate pop instruction discards the element at TOS, so when return is executed, the stack becomes empty (or balanced).

Two-dimensional arrays

Two-dimensional arrays in Java are just one-dimensional arrays of references to another one-dimensional arrays.

Let’s create a two-dimensional array:

```java
public static void main(String[] args) {
    int[][] a = new int[5][10];
    a[1][2]=3;
}
```

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=2, args_size=1
0: iconst_5
1: bipush 10
3: multianewarray #2, 2 // class "[[I"
7: astore_1
8: aload_1
9: iconst_1
10: aaload
11: iconst_2
12: iconst_3
13: iastore
14: return
```

It’s created using the multianewarray instruction: the object’s type and dimensionality are passed as operands.

The array’s size (10*5) is left in stack (using the instructions iconst_5 and bipush).

A reference to row #1 is loaded at offset 10 (iconst_1 and aaload).

The column is chosen using iconst_2 at offset 11.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The value to be written is set at offset 12. 
iastore at 13 writes the array's element.

How it is an element accessed?

```java
public static int get12 (int[][] in)
{
    return in[1][2];
}
```

```java
public static int get12(int[][][]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=1, args_size=1
    0: aload_0
    1: iconst_1
    2: aaload
    3: iconst_2
    4: iaload
    5: ireturn
```

A Reference to the array’s row is loaded at offset 2, the column is set at offset 3, then iaload loads the array's element.

### Three-dimensional arrays

Three-dimensional arrays are just one-dimensional arrays of references to one-dimensional arrays of references.

```java
public static void main(String[] args)
{
    int[][][][] a = new int[5][10][15];
    a[1][2][3]=4;
    get_elem(a);
}
```

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=2, args_size=1
    0: iconst_5
    1: bipush 10
    3: bipush 15
    5: multianewarray #2, 3 // class "[[[I"
    9: astore_1
    10: aload_1
    11: iconst_1
    12: aaload
    13: iconst_2
    14: aaload
    15: iconst_3
    16: aaload
    17: iastore
    18: aaload
    19: invokestatic #3 // Method get_elem:([[[I)I
    22: pop
    23: return
```

Now it takes two aaload instructions to find right reference:

```java
public static int get_elem (int[][][][] a)
{
    return a[1][2][3];
}
```
public static int get_elem(int[][][]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=2, locals=1, args_size=1
  0: aload_0
  1: iconst_1
  2: aaload
  3: iconst_2
  4: aaload
  5: iconst_3
  6: iaload
  7: ireturn

Summary
Is it possible to do a buffer overflow in Java?
No, because the array’s length is always present in an array object, array bounds are controlled, and an
exception is to be raised in case of out-of-bounds access.
There are no multi-dimensional arrays in Java in the C/C++ sense, so Java is not very suited for fast
scientific computations.

4.1.14 Strings
First example
Strings are objects and are constructed in the same way as other objects (and arrays).

public static void main(String[] args)
{
    System.out.println("What is your name?");
    String input = System.console().readLine();
    System.out.println("Hello, "+input);
}

public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=2, args_size=1
  0: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
  3: ldc #3 // String What is your name?
  5: invokevirtual #4 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
  8: invokevirtual #5 // Method java/lang/System.console:()Ljava/io/Console;
 11: invokevirtual #6 // Method java/io/Console.readLine:()Ljava/lang/String;
 14: astore_1
 15: getstatic #2 // Field java/lang/System.out:Ljava/io/PrintStream;
 18: new #7 // class java/lang/StringBuilder
 21: dup
 22: invokespecial #8 // Method java/lang/StringBuilder.<init>():V
 25: ldc #9 // String Hello,
\r;Ljava/lang/StringBuilder;
 30: aload_1
 31: invokevirtual #10 // Method java/lang/StringBuilder.append:(Ljava/lang/String;)
\r;Ljava/lang/StringBuilder;
 34: invokevirtual #11 // Method java/lang/StringBuilder.toString():Ljava/lang/String;
\r;
 37: invokevirtual #4 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
 40: return

The readLine() method is called at offset 11, a reference to string (which is supplied by the user) is then
stored at TOS.
At offset 14 the reference to string is stored in slot 1 of LVA.
The string the user entered is reloaded at offset 30 and concatenated with the “Hello, ” string using the StringBuilder class.

The constructed string is then printed using println at offset 37.

**Second example**

Another example:

```java
public class strings {
    public static char test (String a)
    {
        return a.charAt(3);
    }

    public static String concat (String a, String b)
    {
        return a+b;
    }
}
```

```java
public static char test(java.lang.String);
flags: ACC_PUBLIC, ACC_STATIC
Code:
      stack=2, locals=1, args_size=1
  0: aload_0
  1: iconst_3
  2: invokevirtual #2 // Method java/lang/String.charAt:(I)C
  5: ireturn
```

The string concatenation is performed using StringBuilder:

```java
public static java.lang.String concat(java.lang.String, java.lang.String);
flags: ACC_PUBLIC, ACC_STATIC
Code:
      stack=2, locals=2, args_size=2
  0: new #3 // class java/lang/StringBuilder
  3: dup
  4: invokespecial #4 // Method java/lang/StringBuilder.<init>::()V
  7: aload_0
  8: invokevirtual #5 // Method java/lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/StringBuilder;
 11: aload_1
 12: invokevirtual #5 // Method java/lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/StringBuilder;
 15: invokevirtual #6 // Method java/lang/StringBuilder.toString:()Ljava/lang/String;
 18: areturn
```

Another example:

```java
public static void main(String[] args)
{
    String s="Hello!";
    int n=123;
    System.out.println("s=" + s + " n=" + n);
}
```

And again, the strings are constructed using the StringBuilder class and its append method, then the constructed string is passed to println:

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
      stack=3, locals=3, args_size=1
  0: ldc #2 ;; String Hello!
  2: astore_1
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
4.1.15 Exceptions

Let's rework our Month example (4.1.13 on page 680) a bit:

Listing 4.10: IncorrectMonthException.java

```java
public class IncorrectMonthException extends Exception {
    private int index;

    public IncorrectMonthException(int index) {
        this.index = index;
    }

    public int getIndex() {
        return index;
    }
}
```

Listing 4.11: Month2.java

```java
class Month2 {
    public static String[] months = {
        "January",
        "February",
        "March",
        "April",
        "May",
        "June",
        "July",
        "August",
        "September",
        "October",
        "November",
        "December"
    };

    public static String get_month (int i) throws IncorrectMonthException {
        if (i<0 || i>11)
            throw new IncorrectMonthException(i);
        return months[i];
    }
}
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
```java
public static void main(String[] args) {
    try {
        System.out.println(get_month(100));
    } catch (IncorrectMonthException e) {
        System.out.println("incorrect month index: "+ e.getIndex());
        e.printStackTrace();
    }
}
```

Essentially, IncorrectMonthException.class has just an object constructor and one getter method. The IncorrectMonthException class is derived from Exception, so the IncorrectMonthException constructor first calls the constructor of the Exception class, then it puts incoming integer value into the sole IncorrectMonthException class field:

```java
public IncorrectMonthException(int);
flags: ACC_PUBLIC
Code:
stack=2, locals=2, args_size=2
0: aload_0
1: invokespecial #1 // Method java/lang/Exception."<init>":()V
4: aload_0
5: iload_1
6: putfield #2 // Field index:I
9: return
```

getIndex() is just a getter. A reference to IncorrectMonthException is passed in the zeroth LVA slot (this), aload_0 takes it, getfield loads an integer value from the object, ireturn returns it.

```java
public int getIndex();
flags: ACC_PUBLIC
Code:
stack=1, locals=1, args_size=1
0: aload_0
1: getfield #2 // Field index:I
4: ireturn
```

Now let's take a look at get_month() in Month2.class:

```java
public static java.lang.String get_month(int) throws IncorrectMonthException;
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=1, args_size=1
0: iload_0
1: iflt 10
4: iload_0
5: bipush 11
7: if_icmple 19
10: new #2 // class IncorrectMonthException
13: dup
14: iload_0
15: invokespecial #3 // Method IncorrectMonthException."<init>":(I)V
18: athrow
19: getstatic #4 // Field months:[Ljava/lang/String;
22: iload_0
23: aaload
24: areturn
```

iflt at offset 1 is if less than.

In case of invalid index, a new object is created using the new instruction at offset 10.
The object’s type is passed as an operand to the instruction (which is IncorrectMonthException).

Then its constructor is called, and index is passed via TOS (offset 15).

When the control flow is offset 18, the object is already constructed, so now the athrow instruction takes a reference to the newly constructed object and signals to JVM to find the appropriate exception handler.

The athrow instruction doesn’t return the control flow here, so at offset 19 there is another basic block, not related to exceptions business, where we can get from offset 7.

How do handlers work?

main() in Month2.class:

```java
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=3, locals=2, args_size=1
0: getstatic #5 // Field java/lang/System.out:Ljava/io/PrintStream;
3: bipush 100
5: invokestatic #6 // Method get_month:(I)Ljava/lang/String;
8: invokevirtual #7 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
11: goto 47
14: astore_1
15: getstatic #5 // Field java/lang/System.out:Ljava/io/PrintStream;
18: new #8 // class java/lang/StringBuilder
21: dup
22: invokespecial #9 // Method java/lang/StringBuilder.<init>():V
25: ldc #10 // String incorrect month index:
30: aload_1
31: invokevirtual #12 // Method IncorrectMonthException.getIndex():I
34: invokevirtual #13 // Method java/lang/StringBuilder.append:(I)Ljava/lang/StringBuilder;
37: invokevirtual #14 // Method java/lang/StringBuilder.toString():Ljava/lang/String;
40: invokevirtual #7 // Method java/io/PrintStream.println:(Ljava/lang/String;)V
43: aload_1
44: invokevirtual #15 // Method IncorrectMonthException.printStackTrace():V
47: return
```

Here is the Exception table, which defines that from offsets 0 to 11 (inclusive) an exception IncorrectMonthException may happen, and if it does, the control flow is to be passed to offset 14.

Indeed, the main program ends at offset 11.

At offset 14 the handler starts. It’s not possible to get here, there are no conditional/unconditional jumps to this area.

But JVM will transfer the execution flow here in case of an exception.

The very first astore_1 (at 14) takes the incoming reference to the exception object and stores it in LVA slot 1.

Later, the getIndex() method (of this exception object) will be called at offset 31.

The reference to the current exception object is passed right before that (offset 30).

The rest of the code is does just string manipulation: first the integer value returned by getIndex() is converted to string by the toString() method, then it’s concatenated with the “incorrect month index: " text string (like we saw before), then println() and printStackTrace() are called.

After printStackTrace() finishes, the exception is handled and we can continue with the normal execution.

At offset 47 there is a return which finishes the main() function, but there could be any other code which would execute as if no exceptions were raised.

Here is an example on how IDA shows exception ranges:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
4.16 Classes

Simple class:

Listing 4.15: test.java

```java
public class test {
    public static int a;
    private static int b;

    public test() {
        a=0;
        b=0;
    }
    public static void set_a (int input) {
        a=input;
    }
    public static int get_a () {
        return a;
    }
    public static void set_b (int input) {
        b=input;
    }
    public static int get_b () {
        return b;
    }
}
```

The constructor just sets both fields to zero:

```java
public test();
flags: ACC_PUBLIC
Code:
    stack=1, locals=1, args_size=1
    0: aload_0
    1: invokespecial #1 // Method java/lang/Object."<init>":()V
    4: iconst_0
    5: putstatic #2 // Field a:I
    8: iconst_0
    9: putstatic #3 // Field b:I
   12: return
```

Setter of `a`:

```java
public static void set_a(int);
flags: ACC_PUBLIC, ACC_STATIC
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Code:
```
stack=1, locals=1, args_size=1
0: iload_0
1: putstatic #2     // Field a:I
4: return
```

Getter of a:
```
public static int get_a();
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=1, locals=0, args_size=0
0: getstatic #2     // Field a:I
3: ireturn
```

Setter of b:
```
public static void set_b(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=1, locals=1, args_size=1
0: iload_0
1: putstatic #3     // Field b:I
4: return
```

Getter of b:
```
public static int get_b();
flags: ACC_PUBLIC, ACC_STATIC
Code:
stack=1, locals=0, args_size=0
0: getstatic #3     // Field b:I
3: ireturn
```

There is no difference in the code which works with public and private fields.

But this type information is present in the .class file, and it's not possible to access private fields from everywhere.

Let's create an object and call its method:

Listing 4.16: ex1.java
```
public class ex1
{
    public static void main(String[] args)
    {
        test obj=new test();
        obj.set_a (1234);
        System.out.println(obj.a);
    }
}
```

There is no difference in the code which works with public and private fields.

But this type information is present in the .class file, and it's not possible to access private fields from everywhere.

Let's create an object and call its method:

Listing 4.16: ex1.java
```
public class ex1
{
    public static void main(String[] args)
    {
        test obj=new test();
        obj.set_a (1234);
        System.out.println(obj.a);
    }
}
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
The new instruction creates an object, but doesn’t call the constructor (it is called at offset 4).
The set_a() method is called at offset 16.
The a field is accessed using the getstatic instruction at offset 21.

4.1.17 Simple patching

First example

Let’s proceed with a simple code patching task.

```java
public class nag {
    public static void nag_screen() {
        System.out.println("This program is not registered");
    }
    public static void main(String[] args) {
        System.out.println("Greetings from the mega-software");
        nag_screen();
    }
}
```

How would we remove the printing of “This program is not registered” string?

Let’s load the .class file into IDA:

```
; Segment type: Pure code
    .method public static nag_screen()V
    .limit stack 2
    .line 4
    178 000 002 | getstatic java/lang/System.out Ljava/io/PrintStream; : CODE XREF: main+8P
    018 003     ldc "This program is not registered"
    102 000 004 | invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
    .line 5
    177    return
    ???? ???? ????+ ??? ???? ???
    .end method

; Segment type: Pure code
    .method public static main([Ljava/lang/String;)V
    .limit stack 2
    .limit locals 1
    .line 8
    178 000 002 | getstatic java/lang/System.out Ljava/io/PrintStream;
    018 005     ldc "Greetings from the mega-software"
    102 000 004 | invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
    .line 9
    184 000 006 | invokestatic nag.nag_screen()V
    .line 10
    177    return
```

Figure 4.1: IDA

Let’s patch the first byte of the function to 177 (which is the return instruction’s opcode):
But that doesn’t work (JRE 1.7):

```java
Exception in thread "main" java.lang.VerifyError: Expecting a stack map frame
Exception Details:
Location:
  nag.nag_screen()V @1: nop
Reason:
  Error exists in the bytecode
Bytecode:
  0000000: b100 0212 03b6 0004 b1
at java.lang.Class.getDeclaredMethods0(Native Method)
at java.lang.Class.privateGetDeclaredMethods(Class.java:2615)
at java.lang.Class.getMethod0(Class.java:2856)
at java.lang.Class.getMethod(Class.java:1668)
at sun.launcher.LauncherHelper.getMainMethod(LauncherHelper.java:494)
at sun.launcher.LauncherHelper.checkAndLoadMain(LauncherHelper.java:486)
```

Perhaps JVM has some other checks related to the stack maps.

OK, let’s patch it differently by removing the call to nag():

```java
0 is the opcode for NOP.
```

Now that works!
Second example

Another simple crackme example:

```java
public class password {
    public static void main(String[] args) {
        System.out.println("Please enter the password");
        String input = System.console().readLine();
        if (input.equals("secret")) {
            System.out.println("password is correct");
        } else {
            System.out.println("password is not correct");
        }
    }
}
```

Let's load it in IDA:

![IDA screenshot](Figure 4.4: IDA)

We see here the `ifeq` instruction which does the job.

Its name stands for *if equal*, and this is misnomer, a better name would be `ifz` (*if zero*), i.e., if value at TOS is zero, then do the jump.

In our example, it jumps if the password is not correct (the `equals` method returns `false`, which is `0`).

The very first idea is to patch this instruction.

There are two bytes in `ifeq` opcode, which encode the jump offset.

To make this instruction a NOP, we must set the 3rd byte to the value of 3 (because by adding 3 to the current address we will always jump to the next instruction, since the `ifeq` instruction's length is 3 bytes):

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
That doesn't work (JRE 1.7):

```
Exception in thread "main" java.lang.VerifyError: Expecting a stackmap frame at branch target 24
```

But it must be mentioned that it worked in JRE 1.6.

We can also try to replace to all 3 ifeq opcode bytes with zero bytes (NOP), and it still won't work.

Seems like there are more stack map checks in JRE 1.7.

OK, we'll replace the whole call to the equals method with the `iconst_1` instruction plus a pack of NOPs:

```
(For statistics collecting purposes) if you've read this far, please click here. Thanks!
```
1 needs always to be in the **TOS** when the `ifeq` instruction is executed, so `ifeq` would never jump. This works.

### 4.1.18 Summary

What is missing in Java in comparison to C/C++?

- **Structures**: use classes.
- **Unions**: use class hierarchies.
- **Unsigned data types**: By the way, this makes cryptographic algorithms somewhat harder to implement in Java.
- **Function pointers**.
Chapter 5
Finding important/interesting stuff in the code

Minimalism it is not a prominent feature of modern software.

But not because the programmers are writing a lot, but because a lot of libraries are commonly linked statically to executable files. If all external libraries were shifted into an external DLL files, the world would be different. (Another reason for C++ are the STL and other template libraries.)

Thus, it is very important to determine the origin of a function, if it is from standard library or well-known library (like Boost\(^1\), libpng\(^2\)), or if it is related to what we are trying to find in the code.

It is just absurd to rewrite all code in C/C++ to find what we’re looking for.

One of the primary tasks of a reverse engineer is to find quickly the code he/she needs, and what is not that important.

The IDA disassembler allow us to search among text strings, byte sequences and constants. It is even possible to export the code to .lst or .asm text files and then use grep, awk, etc.

When you try to understand what some code is doing, this easily could be some open-source library like libpng. So when you see some constants or text strings which look familiar, it is always worth to google them. And if you find the opensource project where they are used, then it’s enough just to compare the functions. It may solve some part of the problem.

For example, if a program uses XML files, the first step may be determining which XML library is used for processing, since the standard (or well-known) libraries are usually used instead of self-made one.

For example, the author of these lines once tried to understand how the compression/decompression of network packets works in SAP 6.0. It is a huge software, but a detailed .PDB with debugging information is present, and that is convenient. He finally came to the idea that one of the functions, that was called CsDecomprLZC, was doing the decompression of network packets. Immediately he tried to google its name and he quickly found the function was used in MaxDB (it is an open-source SAP project)\(^3\).

http://www.google.com/search?q=CsDecomprLZC

Astoundingly, MaxDB and SAP 6.0 software shared likewise code for the compression/decompression of network packets.

5.1 Identification of executable files

5.1.1 Microsoft Visual C++

MSVC versions and DLLs that can be imported:

msvcp*.dll has C++-related functions, so if it is imported, this is probably a C++ program.

**Name mangling**

The names usually start with the ? symbol.

You can read more about MSVC’s name mangling here: 3.19.1 on page 549.

### 5.1.2 GCC

Aside from *NIX targets, GCC is also present in the win32 environment, in the form of Cygwin and MinGW.

**Name mangling**

Names usually start with the _Z symbols.

You can read more about GCC’s name mangling here: 3.19.1 on page 549.

**Cygwin**

cygwin1.dll is often imported.

**MinGW**

msvcr.dll may be imported.

### 5.1.3 Intel Fortran

libifcoremd.dll, libifportmd.dll and libiomp5md.dll (OpenMP support) may be imported.

libifcoremd.dll has a lot of functions prefixed with for_, which means Fortran.

### 5.1.4 Watcom, OpenWatcom

**Name mangling**

Names usually start with the W symbol.

For example, that is how the method named “method” of the class “class” that does not have any arguments and returns void is encoded:

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
5.1.5 Borland

Here is an example of Borland Delphi's and C++Builder's name mangling:

@TApplication@IdleAction$qv
@TApplication@ProcessMDIAccels$qp6tagMSG
@TModule@$bctr$qpcpvt1
@TModule@$bdtr$qv
@TModule@ValidWindow$qp14TWindowsObject
@TrueColorTo8BitN$qpviiiiiit1iiiiii
@TrueColorTo16BitN$qpviiiiiit1iiiiii
@DIB24BitTo8BitBitmap$qpviiiiiit1iiiii
@TrueBitmap@$bctr$qpcl
@TrueBitmap@$bctr$qpvl
@TrueBitmap@$bctr$qiilll

The names always start with the @ symbol, then we have the class name came, method name, and encoded the types of the arguments of the method.

These names can be in the .exe imports, .dll exports, debug data, etc.

Borland Visual Component Libraries (VCL) are stored in .bpl files instead of .dll ones, for example, vcl50.dll, rtl60.dll.

Another DLL that might be imported: BORLNDMM.DLL.

Delphi

Almost all Delphi executables has the “Boolean” text string at the beginning of the code segment, along with other type names.

This is a very typical beginning of the CODE segment of a Delphi program, this block came right after the win32 PE file header:

```
00000400 04 10 40 00 03 07 42 6f 6f 6c 65 61 6e 01 00 00 |...Boolean...|

000005c0 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |............|
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
5.1.6 Other known DLLs

- vcomp*.dll—Microsoft’s implementation of OpenMP.

5.2 Communication with outer world (function level)

It’s often advisable to track function arguments and return values in debugger or DBI. For example, the author once tried to understand meaning of some obscure function, which happens to be incorrectly implemented bubble sort. (It worked correctly, but slower.) Meanwhile, watching inputs and outputs of this function helps instantly to understand what it does.

Often, when you see division by multiplication, but forgot all details about its mechanics, you can just observe input and output and quickly find divisor.

5.3 Communication with the outer world (win32)

Sometimes it’s enough to observe some function’s inputs and outputs in order to understand what it does. That way you can save time.

Files and registry access: for the very basic analysis, Process Monitor utility from SysInternals can help. For the basic analysis of network accesses, Wireshark can be useful. But then you will have to look inside anyway.

The first thing to look for is which functions from the OS’s APIs and standard libraries are used. If the program is divided into a main executable file and a group of DLL files, sometimes the names of the functions in these DLLs can help. If we are interested in exactly what can lead to a call to `MessageBox()` with specific text, we can try to find this text in the data segment, find the references to it and find the points from which the control may be passed to the `MessageBox()` call we’re interested in.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
If we are talking about a video game and we’re interested in which events are more or less random in it, we may try to find the `rand()` function or its replacements (like the Mersenne twister algorithm) and find the places from which those functions are called, and more importantly, how are the results used. One example: 8.2 on page 799.

But if it is not a game, and `rand()` is still used, it is also interesting to know why. There are cases of unexpected `rand()` usage in data compression algorithms (for encryption imitation): blog.yurichev.com.

### 5.3.1 Often used functions in the Windows API

These functions may be among the imported. It is worth to note that not every function might be used in the code that was written by the programmer. A lot of functions might be called from library functions and CRT code.

Some functions may have the `-A` suffix for the ASCII version and `-W` for the Unicode version.

- Registry access (advapi32.dll): `RegEnumKeyEx`, `RegEnumValue`, `RegGetValue`, `RegOpenKeyEx`, `RegQueryValueEx`.
- Dialog boxes (user32.dll): `MessageBox`, `MessageBoxEx`, `CreateDialog`, `SetDlgItemText`, `GetDlgItemText`.
- Resources access (6.5.2 on page 763): (user32.dll): `LoadMenu`.
- TCP/IP networking (ws2_32.dll): `WSARecv`, `WSASend`.
- File access (kernel32.dll): `CreateFile`, `ReadFile`, `ReadFileEx`, `WriteFile`, `WriteFileEx`.
- High-level access to the Internet (wininet.dll): `WinHttpOpen`.
- Checking the digital signature of an executable file (wintrust.dll): `WinVerifyTrust`.
- The standard MSVC library (if it’s linked dynamically) (msvcr*.dll): `assert`, `itoa`, `ltoa`, `open`, `printf`, `read`, `strncpy`, `atol`, `atoi`, `fopen`, `fwrite`, `memcmp`, `rand`, `strlen`, `strchr`.

### 5.3.2 Extending trial period

Registry access functions are frequent targets for those who try to crack trial period of some software, which may save installation date/time into registry.

Another popular target are `GetLocalTime()` and `GetSystemTime()` functions: a trial software, at each startup, must check current date/time somehow anyway.

### 5.3.3 Removing nag dialog box

A popular way to find out what causing popping nag dialog box is intercepting `MessageBox()`, `CreateDialog()` and `CreateWindow()` functions.

### 5.3.4 tracer: Intercepting all functions in specific module

There are INT3 breakpoints in the tracer, that are triggered only once, however, they can be set for all functions in a specific DLL.

```
--one-time-INT3-bp:somedll.dll!.*
```

Or, let’s set INT3 breakpoints on all functions with the `xml` prefix in their name:

```
--one-time-INT3-bp:somedll.dll!xml.*
```

On the other side of the coin, such breakpoints are triggered only once. Tracer will show the call of a function, if it happens, but only once. Another drawback—it is impossible to see the function’s arguments.

Nevertheless, this feature is very useful when you know that the program uses a DLL, but you do not know which functions are actually used. And there are a lot of functions.

(For statistics collecting purposes) if you’ve read this far, please click [here](https://blog.yurichev.com). Thanks!
For example, let's see, what does the uptime utility from cygwin use:

```
tracer -l:uptime.exe --one-time-INT3-bp:cygwin1.dll!.*
```

Thus we may see all that cygwin1.dll library functions that were called at least once, and where from:

<table>
<thead>
<tr>
<th>One-time INT3 breakpoint:</th>

</tbody>
</table>

## 5.4 Strings

### 5.4.1 Text strings

**C/C++**

The normal C strings are zero-terminated ([ASCII]-strings).

The reason why the C string format is as it is (zero-terminated) is apparently historical. In [Dennis M. Ritchie, *The Evolution of the Unix Time-sharing System*, (1979)] we read:

```
A minor difference was that the unit of I/O was the word, not the byte, because the PDP-7
was a word-addressed machine. In practice this meant merely that all programs dealing
with character streams ignored null characters, because null was used to pad a file to an
even number of characters.
```

In Hiew or FAR Manager these strings look like this:

```c
int main()
{
    printf ("Hello, world!\n");
}
```

![Figure 5.1: Hiew](image)

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Borland Delphi

The string in Pascal and Borland Delphi is preceded by an 8-bit or 32-bit string length.

For example:

```
Listing 5.1: Delphi

CODE:00518AC8       dd 19h
CODE:00518ACC aLoading___Plea db 'Loading..., please wait.',0
...
CODE:00518AFC       dd 10h
CODE:00518B00 aPreparingRun__ db 'Preparing run...',0
```

Unicode

Often, what is called Unicode is a methods for encoding strings where each character occupies 2 bytes or 16 bits. This is a common terminological mistake. Unicode is a standard for assigning a number to each character in the many writing systems of the world, but does not describe the encoding method.

The most popular encoding methods are: UTF-8 (is widespread in Internet and *NIX systems) and UTF-16LE (is used in Windows).

UTF-8

UTF-8 is one of the most successful methods for encoding characters. All Latin symbols are encoded just like in ASCII, and the symbols beyond the ASCII table are encoded using several bytes. 0 is encoded as before, so all standard C string functions work with UTF-8 strings just like any other string.

Let’s see how the symbols in various languages are encoded in UTF-8 and how it looks like in FAR, using the 437 codepage 7:

```
How much? 100€?
(English) I can eat glass and it doesn't hurt me.
(Greek) Μπορώ να φάω σπάσιμα γυάλια χωρίς να πάω τραυματισμένος.
(Hungarian) Még tudom enni az üveget, nem lesz tőle bajom.
(Icelandic) Eg get eitil ger án þess að meða mig.
(Polish) Mogę jeść szkło i mi nie szkodzi.
(Russian) Я могу есть стекло, это мне не вредит.
(Arabic) أنت قادر على أن تأكل الزجاج وهذا لا يضر لي.
(Hebrew) ואתה יכול לאכול זכוכית והיא לא מקשה.
(Chinese) 能吞下玻璃而不伤身体。
(Japanese) 玻璃を食べられます。それは私の傷つけません。
(Hindi) मैं खाएं जोड़ा सकता हूँ और मुझे उससे कोई घोट नहीं पहुँचती।
```

7The example and translations was taken from here: [http://go.yurichev.com/17304](http://go.yurichev.com/17304)
As you can see, the English language string looks the same as it is in ASCII.

The Hungarian language uses some Latin symbols plus symbols with diacritic marks. These symbols are encoded using several bytes, these are underscored with red. It’s the same story with the Icelandic and Polish languages.

There is also the “Euro” currency symbol at the start, which is encoded with 3 bytes.

The rest of the writing systems here have no connection with Latin.

At least in Russian, Arabic, Hebrew and Hindi we can see some recurring bytes, and that is not surprise: all symbols from a writing system are usually located in the same Unicode table, so their code begins with the same numbers.

At the beginning, before the “How much?” string we see 3 bytes, which are in fact the BOM\(^8\). The BOM defines the encoding system to be used.

**UTF-16LE**

Many win32 functions in Windows have the suffixes -A and -W. The first type of functions works with normal strings, the other with UTF-16LE strings (*wide*).

In the second case, each symbol is usually stored in a 16-bit value of type *short*.

The Latin symbols in UTF-16 strings look in Hiew or FAR like they are interleaved with zero byte:

```c
int wmain()
{
  wprintf (L"Hello, world!\n");
}
```

---

\(^8\) Byte Order Mark

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We can see this often in Windows NT system files:

![Image of Windows NT system files]

Figure 5.4: Hiew

Strings with characters that occupy exactly 2 bytes are called “Unicode” in IDA:

```
.data:0040E000 aHelloWorld:
.data:0040E000          unicode 0, <Hello, world!>
.data:0040E000          dw 0Ah, 0
```

Here is how the Russian language string is encoded in UTF-16LE:

![Image of UTF-16LE encoding]

Figure 5.5: Hiew: UTF-16LE

What we can easily spot is that the symbols are interleaved by the diamond character (which has the ASCII code of 4). Indeed, the Cyrillic symbols are located in the fourth Unicode plane. Hence, all Cyrillic symbols in UTF-16LE are located in the 0x400-0x4FF range.

Let's go back to the example with the string written in multiple languages. Here is how it looks like in UTF-16LE.

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Figure 5.6: FAR: UTF-16LE

Here we can also see the BOM at the beginning. All Latin characters are interleaved with a zero byte. Some characters with diacritic marks (Hungarian and Icelandic languages) are also underscored in red.

**Base64**

The base64 encoding is highly popular for the cases when you have to transfer binary data as a text string. In essence, this algorithm encodes 3 binary bytes into 4 printable characters: all 26 Latin letters (both lower and upper case), digits, plus sign (“+”) and slash sign (“/”), 64 characters in total.

One distinctive feature of base64 strings is that they often (but not always) end with 1 or 2 *padding* equality symbol(s) (“=”), for example:

```
AVjbbVSVfcUMu1xvjaMgjNtueRwBxnyJw8dpGnLW8ZW8aKG3v4Y0icuQT+qEJAp9lAOuWs=
WVjbbVSVfcUMu1xvjaMgjNtueRwBxnyJw8dpGnLW8ZW8aKG3v4Y0icuQT+qEJAp9lAOuQ==
```

The equality sign (“=”) is never encountered in the middle of base64-encoded strings.

Now example of manual encoding. Let’s encode 0x00, 0x11, 0x22, 0x33 hexadecimal bytes into base64 string:

```
$ echo -n "\x00\x11\x22\x33" | base64
ABEiMw==
```

Let’s put all 4 bytes in binary form, then regroup them into 6-bit groups:

```
| 00 || 11 || 22 || 33 || || |
0000000000010000100100011001111111111
| A || B || E || i || M || w || = || = |
```

Three first bytes (0x00, 0x11, 0x22) can be encoded into 4 base64 characters (“ABEi”), but the last one (0x33) — cannot be, so it’s encoded using two characters (“Mw”) and *padding* symbol (“=”). Hence, length of all correct base64 strings are always divisible by 4.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Base64 is often used when binary data needs to be stored in XML. “Armored” (i.e., in text form) PGP keys and signatures are encoded using base64.

There are utilities for scanning an arbitrary binary files for base64 strings. One such utility is base64scanner[^11].

Another encoding system which was much more popular in Usenet and FidoNet is Uuencoding. Binary files are still encoded in Uuencode format in Phrack magazine. It offers mostly the same features, but is different from base64 in the sense that file name is also stored in header.

By the way: there is also close sibling to base64: base32, alphabet of which has 10 digits and 26 Latin characters. One well-known usage of it is onion addresses[^12], like: [http://3g2upl4pq6kufc4m.onion/](http://3g2upl4pq6kufc4m.onion/). URL can’t have mixed-case Latin characters, so apparently, this is why Tor developers used base32.

### 5.4.2 Finding strings in binary

Actually, the best form of Unix documentation is frequently running the `strings` command over a program’s object code. Using `strings`, you can get a complete list of the program’s hard-coded file name, environment variables, undocumented options, obscure error messages, and so forth.

The standard UNIX `strings` utility is quick-n-dirty way to see strings in file. For example, these are some strings from OpenSSH 7.2 sshd executable file:

```
... 0123 0123456789 0123456789abcdefABCDEF.:/ %02x ...
%.100s, line %lu: Bad permitopen specification <%.100s>
%.100s, line %lu: invalid criteria
%.100s, line %lu: invalid tun device ...
%.200s/.ssh/environment ...
2886173b9c9b6fbd3eda7a247cd636db38deaa.debug $2a$s06$r3.juUaHZdJIbQa02s59FuYxL1w9MB1R1Tc2PoSNmzvpEqLkLGK ...
3des-cbc ...
Bind to port %s on %s.
Bind to port %s on %s failed: %.200s./bin/login /bin/sh /bin/sh /etc/ssh/sshrc ...
D$4PQWR1 D$4PUj D$4PV D$4PVj D$4PW D$4PWj D$4X D$4XZj D$4Y ...
```

[^10]: [http://archive.is/nDCas](http://archive.is/nDCas)
[^11]: [https://github.com/DennisYurichev/base64scanner](https://github.com/DennisYurichev/base64scanner)
There are options, error messages, file paths, imported dynamic modules and functions, some other strange strings (keys?) There is also unreadable noise—x86 code sometimes has chunks consisting of printable ASCII characters, up to 8 characters.

Of course, OpenSSH is open-source program. But looking at readable strings inside of some unknown binary is often a first step of analysis.

grep can be applied as well.

Hiew has the same capability (Alt-F6), as well as Sysinternals ProcessMonitor.

### 5.4.3 Error/debug messages

Debugging messages are very helpful if present. In some sense, the debugging messages are reporting what’s going on in the program right now. Often these are printf()-like functions, which write to log-files, or sometimes do not writing anything but the calls are still present since the build is not a debug one but release one.

If local or global variables are dumped in debug messages, it might be helpful as well since it is possible to get at least the variable names. For example, one of such function in Oracle RDBMS is ksdwr().

Meaningful text strings are often helpful. The IDA disassembler may show from which function and from which point this specific string is used. Funny cases sometimes happen.

The error messages may help us as well. In Oracle RDBMS, errors are reported using a group of functions. You can read more about them here: [blog.yurichev.com](http://blog.yurichev.com).

It is possible to find quickly which functions report errors and in which conditions.

By the way, this is often the reason for copy-protection systems to inarticulate cryptic error messages or just error numbers. No one is happy when the software cracker quickly understand why the copy-protection is triggered just by the error message.

One example of encrypted error messages is here: [8.5.2 on page 822](http://blog.yurichev.com).

### 5.4.4 Suspicious magic strings

Some magic strings which are usually used in backdoors look pretty suspicious.

For example, there was a backdoor in the TP-Link WR740 home router. The backdoor can activated using the following URL: [http://192.168.0.1/userRpmNatDebugRpm26525557/start_art.html](http://192.168.0.1/userRpmNatDebugRpm26525557/start_art.html).

Indeed, the “userRpmNatDebugRpm26525557” string is present in the firmware.

This string was not googleable until the wide disclosure of information about the backdoor.

You would not find this in any [RFC](http://www.ietf.org/rfc/rfc15).

You would not find any computer science algorithm which uses such strange byte sequences.

And it doesn’t look like an error or debugging message.

So it’s a good idea to inspect the usage of such weird strings.

---

13 [blog.yurichev.com](http://blog.yurichev.com)
15 Request for Comments
Sometimes, such strings are encoded using base64. So it’s a good idea to decode them all and to scan them visually, even a glance should be enough.

More precise, this method of hiding backdoors is called “security through obscurity”.

### 5.5 Calls to assert()

Sometimes the presence of the assert() macro is useful too: commonly this macro leaves source file name, line number and condition in the code.

The most useful information is contained in the assert’s condition, we can deduce variable names or structure field names from it. Another useful piece of information are the file names—we can try to deduce what type of code is there. Also it is possible to recognize well-known open-source libraries by the file names.

Listing 5.2: Example of informative assert() calls

```asm
.text:107D4B29 mov dx, [ecx+42h]
.text:107D4B2D cmp edx, 1
.text:107D4B30 jz short loc_107D4B4A
.text:107D4B32 push 1EH
.text:107D4B37 push offset aWrite_c ; "write.c"
.text:107D4B3C push offset aTdTd_planarcon ; "td->td_planarconfig == PLANARCONFIG_CON"
... call ds:_assert

.text:107D52CA mov edx, [ebp-4]
.text:107D52CD and edx, 3
.text:107D52D0 test edx, edx
.text:107D52D2 jz short loc_107D52E9
.text:107D52D4 push 50h
.text:107D52D6 push offset aDumpmode_c ; "dumpmode.c"
.text:107D52DB push offset aN30 ; "(n & 3) == 0"
... call ds:_assert

.text:107D6759 mov cx, [eax+6]
.text:107D675D cmp ecx, 0Ch
.text:107D6760 jle short loc_107D677A
.text:107D6762 push 208h
.text:107D6767 push offset aLzw_c ; "lzw.c"
.text:107D676C push offset aSpLzw_lbitsBit ; "sp->lzw_nbits <= BITS_MAX"
.text:107D6771 call ds:_assert
```

It is advisable to “google” both the conditions and file names, which can lead us to an open-source library. For example, if we “google” “sp->lzw_nbits <= BITS_MAX”, this predictably gives us some open-source code that’s related to the LZW compression.

### 5.6 Constants

Humans, including programmers, often use round numbers like 10, 100, 1000, in real life as well as in the code.

The practicing reverse engineer usually know them well in hexadecimal representation: 10=0xA, 100=0x64, 1000=0x3E8, 10000=0x2710.

The constants 0xAAAAAAAA (0b10101010101010101010101010101010) and 0x55555555 (0b01010101010101010101010101010101) are also popular—those are composed of alternating bits.
That may help to distinguish some signal from a signal where all bits are turned on (0b1111 ...) or off (0b0000 ...). For example, the 0x55AA constant is used at least in the boot sector, MBR\textsuperscript{16}, and in the ROM of IBM-compatible extension cards. Some algorithms, especially cryptographical ones use distinct constants, which are easy to find in code using IDA.

For example, the MD5\textsuperscript{17} algorithm initializes its own internal variables like this:

\begin{verbatim}
var int h0 := 0x67452301
var int h1 := 0xEFCDAB89
var int h2 := 0x98BADCFE
var int h3 := 0x10325476
\end{verbatim}

If you find these four constants used in the code in a row, it is highly probable that this function is related to MD5.

Another example are the CRC16/CRC32 algorithms, whose calculation algorithms often use precomputed tables like this one:

\begin{verbatim}
/* CRC table for the CRC-16. The poly is 0x8005 (x^16 + x^15 + x^2 + 1) */
const u16 crc16_table[256] = {
    0x0000, 0xC0C1, 0xC181, 0x0140, 0xC301, 0x03C0, 0x0280, 0xC241,
    0xC601, 0x06C0, 0x0780, 0xC741, 0x0500, 0xC5C1, 0xC481, 0x0440,
    0xCC01, 0x0CC0, 0x0080, 0xCD41, 0x0F00, 0xCFC1, 0xCE81, 0x0E40,
    ...}
\end{verbatim}

See also the precomputed table for CRC32: 3.6 on page 489.

In tableless CRC algorithms well-known polynomials are used, for example, 0xEDB88320 for CRC32.

5.6.1 Magic numbers

A lot of file formats define a standard file header where a magic number(s)\textsuperscript{18} is used, single one or even several.

For example, all Win32 and MS-DOS executables start with the two characters “MZ”\textsuperscript{19}.

At the beginning of a MIDI file the “MThd” signature must be present. If we have a program which uses MIDI files for something, it’s very likely that it must check the file for validity by checking at least the first 4 bytes.

This could be done like this: (buf points to the beginning of the loaded file in memory)

\begin{verbatim}
cmp [buf], 0x6468544D ; "MThd"
jnz _error_not_a_MIDI_file
\end{verbatim}

...or by calling a function for comparing memory blocks like memcmp() or any other equivalent code up to a CMPSB (1.6 on page 1005) instruction.

When you find such point you already can say where the loading of the MIDI file starts, also, we could see the location of the buffer with the contents of the MIDI file, what is used from the buffer, and how.

Dates

Often, one may encounter number like 0x19870116, which is clearly looks like a date (year 1987, 1th month (January), 16th day). This may be someone’s birthday (a programmer, his/her relative, child), or some other important date. The date may also be written in a reverse order, like 0x16011987. American-style dates are also popular, like 0x01161987.

Well-known example is 0x19540119 (magic number used in UFS2 superblock structure), which is a birthday of Marshall Kirk McKusick, prominent FreeBSD contributor.

\textsuperscript{16}Master Boot Record \hfill \textsuperscript{17}wikipedia \hfill \textsuperscript{18}wikipedia \hfill \textsuperscript{19}wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Stuxnet uses the number “19790509” (not as 32-bit number, but as string, though), and this led to speculation that the malware is connected to Israel.\textsuperscript{20} Also, numbers like those are very popular in amateur-grade cryptography, for example, excerpt from the secret function internals from HASP3 dongle:\textsuperscript{21}

\begin{verbatim}
void xor_pwd(void)
{
    int i;
    pwd ^= 0x09071966;
    for(i=0; i<8; i++)
    {
        al_buf[i] = pwd & 7; pwd = pwd >> 3;
    }
}

void emulate_func2(unsigned short seed)
{
    int i, j;
    for(i=0; i<8; i++)
    {
        ch[i] = 0;
        for(j=0; j<8; j++)
        {
            seed *= 0x1989;
            seed += 5;
            ch[i] |= (tab[(seed>>9)&0x3f]) << (7-j);
        }
    }
}
\end{verbatim}

**DHCP**

This applies to network protocols as well. For example, the DHCP protocol's network packets contains the so-called magic cookie: 0x63538263. Any code that generates DHCP packets somewhere must embed this constant into the packet. If we find it in the code we may find where this happens and, not only that. Any program which can receive DHCP packet must verify the magic cookie, comparing it with the constant.

For example, let's take the dhcpcore.dll file from Windows 7 x64 and search for the constant. And we can find it, twice: it seems that the constant is used in two functions with descriptive names DhcpExtractOptionsForValidation() and DhcpExtractFullOptions():

```
Listing 5.4: dhcpcore.dll (Windows 7 x64)
.rdata:000007FF6483CBE8 dword 7FF6483CBE8 dd 63538263h ; DATA XREF:
DhcpExtractOptionsForValidation+79
.rdata:000007FF6483CBEC dword 7FF6483CBEC dd 63538263h ; DATA XREF:
DhcpExtractFullOptions+97
```

And here are the places where these constants are accessed:

```
Listing 5.5: dhcpcore.dll (Windows 7 x64)
.text:000007FF6480875F mov  eax, [rsi]
.text:000007FF64808761 cmp  eax, cs:dword 7FF6483CBE8
.text:000007FF64808767 jnz  loc_7FF64817179
```

And:

```
Listing 5.6: dhcpcore.dll (Windows 7 x64)
.text:000007FF648082C7 mov  eax, [r12]
.text:000007FF648082CB cmp  eax, cs:dword 7FF6483CBE
.text:000007FF648082D1 jnz  loc_7FF648173AF
```

\textsuperscript{20}This is a date of execution of Habib Elghanian, persian jew.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
5.6.2 Specific constants

Sometimes, there is a specific constant for some type of code. For example, the author once dug into a code, where number 12 was encountered suspiciously often. Size of many arrays is 12, or multiple of 12 (24, etc). As it turned out, that code takes 12-channel audio file at input and process it.

And vice versa: for example, if a program works with text field which has length of 120 bytes, there has to be a constant 120 or 119 somewhere in the code. If UTF-16 is used, then $2 \cdot 120$. If a code works with network packets of fixed size, it’s good idea to search for this constant in the code as well.

This is also true for amateur cryptography (license keys, etc). If encrypted block has size of $n$ bytes, you may want to try to find occurrences of this number throughout the code. Also, if you see a piece of code which is been repeated $n$ times in loop during execution, this may be encryption/decryption routine.

5.6.3 Searching for constants

It is easy in IDA: Alt-B or Alt-I. And for searching for a constant in a big pile of files, or for searching in non-executable files, there is a small utility called binary grep.

5.7 Finding the right instructions

If the program is utilizing FPU instructions and there are very few of them in the code, one can try to check each one manually with a debugger.

For example, we may be interested how Microsoft Excel calculates the formulae entered by user. For example, the division operation.

If we load excel.exe (from Office 2010) version 14.0.4756.1000 into IDA, make a full listing and to find every FDIV instruction (except the ones which use constants as a second operand—obviously, they do not suit us):

```
cat EXCEL.lst | grep fdiv | grep -v dbl_ > EXCEL.fdiv
```

...then we see that there are 144 of them.

We can enter a string like $(1/3)$ in Excel and check each instruction.

By checking each instruction in a debugger or tracer (one may check 4 instruction at a time), we get lucky and the sought-for instruction is just the 14th:

```
.text:3011E919 DC 33    fdiv    qword ptr [ebx]
```

The instruction after FDIV (FSTP) writes the result in memory:

```
.text:3011E91B DD 1E    fstp    qword ptr [esi]
```

If we set a breakpoint on it, we can see the result:

---

GitHub

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Also as a practical joke, we can modify it on the fly:

```
tracer -l:excel.exe bpx=excel.exe!BASE+0x11E91B,set(st0,666)
```

Excel shows 666 in the cell, finally convincing us that we have found the right point.

If we try the same Excel version, but in x64, we will find only 12 FDIV instructions there, and the one we are looking for is the third one.

```
tracer.exe -l:excel.exe bpx=excel.exe!BASE+0x1B7FCC,set(st0,666)
```

It seems that a lot of division operations of float and double types, were replaced by the compiler with SSE instructions like DIVSD (DIVSD is present 268 times in total).

### 5.8 Suspicious code patterns

#### 5.8.1 XOR instructions

Instructions like XOR op, op (for example, XOR EAX, EAX) are usually used for setting the register value to zero, but if the operands are different, the “exclusive or” operation is executed.
This operation is rare in common programming, but widespread in cryptography, including amateur one. It’s especially suspicious if the second operand is a big number.

This may point to encrypting/decrypting, checksum computing, etc.

One exception to this observation worth noting is the “canary” (1.26.3 on page 283). Its generation and checking are often done using the XOR instruction.

This AWK script can be used for processing IDA listing (.lst) files:

```
gawk -e '$2=="xor" { tmp=substr($3, 0, length($3)-1); if (tmp!=$4) if($4!="esp") if ($4!="ebp") 
⤦
⤦  { print $1, $2, tmp, ",", $4 } }' filename.lst
```

It is also worth noting that this kind of script can also match incorrectly disassembled code (5.11.1 on page 726).

### 5.8.2 Hand-written assembly code

Modern compilers do not emit the LOOP and RCL instructions. On the other hand, these instructions are well-known to coders who like to code directly in assembly language. If you spot these, it can be said that there is a high probability that this fragment of code was hand-written. Such instructions are marked as (M) in the instructions list in this appendix: .1.6 on page 999.

Also the function prologue/epilogue are not commonly present in hand-written assembly.

Commonly there is no fixed system for passing arguments to functions in the hand-written code.

Example from the Windows 2003 kernel (ntoskrnl.exe file):

```assembly
MultiplyTest proc near ; CODE XREF: Get386Stepping
    xor    cx, cx
loc_620555:
    push   cx
    call   Multiply
    pop    cx
    jb     short locret_620563
    loop   loc_620555
    clc
locret_620563:
    ret
MultiplyTest endp

Multiply proc near ; CODE XREF: MultiplyTest+5
    mov    ecx, 81h
    mov    eax, 417A000h
    mul    ecx
    cmp    edx, 2
    stc
    jnz    short locret_62057F
    cmp    eax, 0FE7A000h
    stc
    jnz    short locret_62057F
    clc
locret_62057F:    ; CODE XREF: Multiply+10
    ; Multiply+18
Multiply endp
```

Indeed, if we look in the WRK\(^{23}\) v1.2 source code, this code can be found easily in file WRK-v1.2\base\ntos\kel\386\icpu.asm.

\(^{23}\)Windows Research Kernel
5.9 Using magic numbers while tracing

Often, our main goal is to understand how the program uses a value that has been either read from file or received via network. The manual tracing of a value is often a very labor-intensive task. One of the simplest techniques for this (although not 100% reliable) is to use your own *magic number*.

This resembles X-ray computed tomography in some sense: a radiocontrast agent is injected into the patient’s blood, which is then used to improve the visibility of the patient’s internal structure in to the X-rays. It is well known how the blood of healthy humans percolates in the kidneys and if the agent is in the blood, it can be easily seen on tomography, how blood is percolating, and are there any stones or tumors.

We can take a 32-bit number like 0x0badf00d, or someone’s birth date like 0x11101979 and write this 4-byte number to some point in a file used by the program we investigate.

Then, while tracing this program with tracer in code coverage mode, with the help of grep or just by searching in the text file (of tracing results), we can easily see where the value has been used and how.

Example of grepable tracer results in cc mode:

```
0x150bf66 (kziaia+0x14), e= 1 [MOV EBX, [EBP+8]] [EBP+8]=0xf59c934
0x150bf69 (kziaia+0x17), e= 1 [MOV EDX, [69AEB08h]] [69AEB08h]=0
0x150bf6f (kziaia+0x1d), e= 1 [FS: MOV EAX, [2Ch]]
0x150bf75 (kziaia+0x23), e= 1 [MOV ECX, [EAX+EDX*4]] [EAX+EDX*4]=0xf1ac360
0x150bf78 (kziaia+0x26), e= 1 [MOV [EBP-4], ECX] ECX=0xf1ac360
```

This can be used for network packets as well. It is important for the *magic number* to be unique and not to be present in the program’s code.

Aside of the tracer, DosBox (MS-DOS emulator) in heavydebug mode is able to write information about all registers’ states for each executed instruction of the program to a plain text file, so this technique may be useful for DOS programs as well.

5.10 Loops

Whenever your program works with some kind of file, or buffer of some size, it has to be some kind of decrypting/processing loop inside of the code.

This is a real example of tracer tool output. There was a code which loads some kind of encrypted file of 258 bytes. I run it with the intention to get each instruction counts (a DBI tool will serve much better these days). And I quickly found a piece of code, which executed 259/258 times:

```
0x45a6b5 e= 1 [FS: MOV [0], EAX] EAX=0x218fb08
0x45a6bb e= 1 [MOV [EBP-254h], ECX] ECX=0x218fbd8
0x45a6c1 e= 1 [MOV EAX, [EBP-254h]] [EBP-254h]=0x218fbd8
0x45a6c7 e= 1 [CMP [EAX+14h], 0] [EAX+14h]=0x102
0x45a6cb e= 1 [JZ 45A9F2h] ZF=false
0x45a6d1 e= 1 [MOV [EBP-00h], 1]
0x45a6d5 e= 1 [XOR ECX, ECX] ECX=0x218fbd8
0x45a6d7 e= 1 [MOV [EBP-14h], CX] CX=0
0x45a6db e= 1 [MOV [EBP-18h], 0]
0x45a6e2 e= 1 [JMP 45A6EDh]
0x45a6e4 e= 258 [MOV EDX, [EBP-18h]] [EBP-18h]=0..5 (248 items skipped) 0xfd..0x101
0x45a6e7 e= 258 [ADD EDX, 1] EDX=0..5 (248 items skipped) 0xfd..0x101
0x45a6ea e= 258 [MOV [EBP-18h], EDX] EDX=1..6 (248 items skipped) 0xfe..0x102
0x45a6ed e= 259 [MOV EAX, [EBP-254h]] [EBP-254h]=0x218fbd8
0x45a6f3 e= 259 [MOV ECX, [EBP-18h]] [EBP-18h]=0..5 (249 items skipped) 0xfe..0x102
0x45a6f6 e= 259 [CMP ECX, [EAX+14h]] ECX=0..5 (249 items skipped) 0xfe..0x102 [EAX+14h]=0x102
0x45a6f9 e= 259 [JNB 45A727h] CF=false,true
0x45a701 e= 258 [MOV EDX, [EBP-18h]] [EBP-18h]=0..5 (248 items skipped) 0xfd..0x101
0x45a704 e= 258 [MOV [EBP-18h], EDX] EDX=1..6 (248 items skipped) 0xfe..0x102
0x45a707 e= 258 [ADD ECX, 1] ECX=0..5 (248 items skipped) 0xfd..0x101
0x45a70a e= 258 [IMUL ECX, ECX, 1Fh] ECX=1..6 (248 items skipped) 0xfe..0x102
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
As it turns out, this is the decrypting loop.

### 5.10.1 Some binary file patterns

All examples here were prepared on the Windows with active code page 437\(^\text{25}\) in console. Binary files internally may look visually different if another code page is set.

\(^{25}\text{https://en.wikipedia.org/wiki/Code_page_437}\)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Arrays

Sometimes, we can clearly spot an array of 16/32/64-bit values visually, in hex editor.

Here is an example of array of 16-bit values. We see that the first byte in pair is 7 or 8, and the second looks random:

![Figure 5.8: FAR: array of 16-bit values](image)

I used a file containing 12-channel signal digitized using 16-bit ADC\(^{26}\).

\(^{26}\)Analog-to-Digital Converter
And here is an example of very typical MIPS code.

As we may recall, every MIPS (and also ARM in ARM mode or ARM64) instruction has size of 32 bits (or 4 bytes), so such code is array of 32-bit values.

By looking at this screenshot, we may see some kind of pattern.

Vertical red lines are added for clarity:

![Hiew: FW96650A.bin](image)

Figure 5.9: Hiew: very typical MIPS code

Another example of such pattern here is book: 9.5 on page 945.
Sparse files

This is sparse file with data scattered amidst almost empty file. Each space character here is in fact zero byte (which is looks like space). This is a file to program FPGA (Altera Stratix GX device). Of course, files like these can be compressed easily, but formats like this one are very popular in scientific and engineering software where efficient access is important while compactness is not.

Figure 5.10: FAR: Sparse file
This file is just some compressed archive. It has relatively high entropy and visually looks just chaotic. This is how compressed and/or encrypted files looks like.

Figure 5.11: FAR: Compressed file

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
OS installations are usually distributed as ISO files which are copies of CD/DVD discs. Filesystem used is named **CDFS**, here is how you see file names mixed with some additional data. This can be file sizes, pointers to another directories, file attributes, etc. This is how typical filesystems may look internally.

---

Figure 5.12: FAR: ISO file: Ubuntu 15 installation **CD**

---

27Compact Disc File System

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
This is how 32-bit x86 executable code looks like. It has not very high entropy, because some bytes occurred more often than others.
BMP graphics files

BMP files are not compressed, so each byte (or group of bytes) describes each pixel. I’ve found this picture somewhere inside my installed Windows 8.1:

![Example picture](image_url)

Figure 5.14: Example picture

You see that this picture has some pixels which unlikely can be compressed very good (around center), but there are long one-color lines at top and bottom. Indeed, lines like these also looks as lines during viewing the file:

![BMP file fragment](image_url)

Figure 5.15: BMP file fragment

5.10.2 Memory “snapshots” comparing

The technique of the straightforward comparison of two memory snapshots in order to see changes was often used to hack 8-bit computer games and for hacking “high score” files.
For example, if you had a loaded game on an 8-bit computer (there isn’t much memory on these, but the
game usually consumes even less memory) and you know that you have now, let’s say, 100 bullets, you
can do a “snapshot” of all memory and back it up to some place. Then shoot once, the bullet count goes
to 99, do a second “snapshot” and then compare both: it must be a byte somewhere which has been 100
at the beginning, and now it is 99.

Considering the fact that these 8-bit games were often written in assembly language and such variables
were global, it can be said for sure which address in memory has holding the bullet count. If you searched
for all references to the address in the disassembled game code, it was not very hard to find a piece of
code decrementing the bullet count, then to write a NOP instruction there, or a couple of NOP-s, and then
have a game with 100 bullets forever. Games on these 8-bit computers were commonly loaded at the
constant address, also, there were not much different versions of each game (commonly just one version
was popular for a long span of time), so enthusiastic gamers knew which bytes must be overwritten (using
the BASIC’s instruction POKE) at which address in order to hack it. This led to “cheat” lists that contained
POKE instructions, published in magazines related to 8-bit games. See also: wikipedia.

Likewise, it is easy to modify “high score” files, this does not work with just 8-bit games. Notice your score
count and back up the file somewhere. When the “high score” count gets different, just compare the two
files, it can even be done with the DOS utility FC29 (“high score” files are often in binary form).

There will be a point where a couple of bytes are different and it is easy to see which ones are holding
the score number. However, game developers are fully aware of such tricks and may defend the program
against it.

Somewhat similar example in this book is: 9.3 on page 933.

A real story from 1999

There was a time of ICQ messenger’s popularity, at least in ex-USSR countries. The messenger had a
peculiarity — some users didn’t want to share their online status with everyone. And you had to ask an
authorization from that user. That user could allow you seeing his/her status, or maybe not.

This is what the author of these lines did:

• Added a user.
• A user appeared in a contact-list, in a “wait for authorization” section.
• Closed ICQ.
• Backed up the ICQ database.
• Loaded ICQ again.
• User authorized.
• Closed ICQ and compared two databases.

It turned out: two database differed by only one byte. In the first version: RESU\x03, in the second:
RESU\x02. (“RESU”, presumably, means “USER”, i.e., a header of a structure where all the information
about user was stored.) That means the information about authorization was stored not at the server, but
at the client. Presumably, 2/3 value reflected authorization status.

Windows registry

It is also possible to compare the Windows registry before and after a program installation.

It is a very popular method of finding which registry elements are used by the program. Perhaps, this is
the reason why the “windows registry cleaner” shareware is so popular.

By the way, this is how to dump Windows registry to text files:

```
reg export HKLM HKLM.reg
reg export HKCU HKCU.reg
reg export HKCR HKCR.reg
reg export HKU HKU.reg
reg export HKCC HKCC.reg
```

They can be compared using diff...

29MS-DOS utility for comparing binary files

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Blink-comparator

Comparison of files or memory snapshots remind us blink-comparator \(^{30}\): a device used by astronomers in past, intended to find moving celestial objects.

Blink-comparator allows to switch quickly between two photographies shot in different time, so astronomer would spot the difference visually.

By the way, Pluto was discovered by blink-comparator in 1930.

### 5.11 ISA detection

Often, you can deal with a binary file for an unknown ISA. Perhaps, easiest way to detect ISA is to try various ones in IDA, objdump or another disassembler.

To achieve this, one should understand a difference between incorrectly disassembled code and correctly one.

#### 5.11.1 Incorrectly disassembled code

Practicing reverse engineers often have to deal with incorrectly disassembled code.

**Disassembling from an incorrect start (x86)**

Unlike ARM and MIPS (where any instruction has a length of 2 or 4 bytes), x86 instructions have variable size, so any disassembler that starts in the middle of a x86 instruction may produce incorrect results.

As an example:

```
add    [ebp-31F7Bh], cl
dec    dword ptr [ecx-3277Bh]
dec    dword ptr [ebp-2CF7Bh]
inc    dword ptr [ebx-7A76F33Ch]
fdiv   st(4), st
db     0FFh
dec    dword ptr [ecx-21F7Bh]
dec    dword ptr [ecx-22373h]
dec    dword ptr [ecx-2276Bh]
dec    dword ptr [ecx-22B63h]
dec    dword ptr [ecx-22F4Bh]
dec    dword ptr [ecx-23343h]
jmp    dword ptr [esi-74h]
xchg   eax, ebp
clc
std
db     0FFh
db     0FFh
mov    word ptr [ebp-21A4h], cs ; <- disassembler finally found right track here
mov    word ptr [ebp-238h], ds
mov    word ptr [ebp-23Ch], es
mov    word ptr [ebp-240h], fs
mov    word ptr [ebp-244h], gs
pushf
pop    dword ptr [ebp-210h]
mov    eax, [ebp+4]
mov    [ebp-218h], eax
lea    eax, [ebp+4]
mov    [ebp-20Ch], eax
mov    dword ptr [ebp-200h], 10001h
mov    eax, [eax-4]
mov    [ebp-21Ch], eax
mov    eax, [ebp+0Ch]
mov    [ebp-320h], eax
```

\(^{30}\) [http://go.yurichev.com/17348](http://go.yurichev.com/17348)

(For statistics collecting purposes) if you've read this far, please click [here](http://go.yurichev.com/17348). Thanks!
mov eax, [ebp+10h]
mov [ebp-31Ch], eax
mov eax, [ebp+4]
mov [ebp-314h], eax
call ds:IsDebuggerPresent
mov edi, eax
lea eax, [ebp-328h]
push eax
call sub_407663
pop ecx
test eax, eax
jnz short loc_402D7B

There are incorrectly disassembled instructions at the beginning, but eventually the disassembler gets on the right track.

**How does random noise looks disassembled?**

Common properties that can be spotted easily are:

- Unusually big instruction dispersion. The most frequent x86 instructions are PUSH, MOV, CALL, but here we see instructions from all instruction groups: FPU instructions, IN/OUT instructions, rare and system instructions, everything mixed up in one single place.

- Big and random values, offsets and immediates.

- Jumps having incorrect offsets, often jumping in the middle of another instructions.

Listing 5.7: random noise (x86)

It is also important to keep in mind that cleverly constructed unpacking and decryption code (including self-modifying) may look like noise as well, but still execute correctly.

5.11.2 Correctly disassembled code

Each ISA has a dozen of a most used instructions, all the rest are used much less often.

As of x86, it is interesting to know that the fact that function calls (PUSH/CALL/ADD) and MOV instructions are the most frequently executed pieces of code in almost all programs we use. In other words, CPU is very busy passing information between levels of abstractions, or, it can be said, it's very busy switching between these levels. Regardless type of ISA. This is a cost of splitting problems into several levels of abstractions (so humans could work with them easier).

5.12 Other things

5.12.1 General idea

A reverse engineer should try to be in programmer’s shoes as often as possible. To take his/her viewpoint and ask himself, how would one solve some task the specific case.

5.12.2 Order of functions in binary code

All functions located in a single .c or .cpp-file are compiled into corresponding object (.o) file. Later, a linker puts all object files it needs together, not changing order of functions in them. As a consequence, if you see two or more consecutive functions, it means, that they were placed together in a single source code file (unless you’re on border of two object files, of course.) This means these functions have something in common, that they are from the same API level, from the same library, etc.

This is a real story from practice: once upon a time, the author searched for Twofish-related functions in a program with CryptoPP library linked, especially encryption/decryption functions.

I found the Twofish::Base::UncheckedSetKey() function, but not others. After peeking into the twofish.cpp source code 31, it became clear that all functions are located in one module (twofish.cpp).

So I tried all function that followed Twofish::Base::UncheckedSetKey()—as it happened, one was Twofish::Enc::ProcessAndXorBlock(), another—Twofish::Dec::ProcessAndXorBlock().

5.12.3 Tiny functions

Tiny functions like empty functions (1.3 on page 5) or function which returns just “true” (1) or “false” (0) (1.4 on page 7) are very common, and almost all decent compilers tend to put only one such function into resulting executable code even if there were several similar functions in source code. So, whenever you see a tiny function consisting just of mov eax, 1 / ret which is referenced (and can be called) from many places, which are seems unconnected to each other, this may be a result of such optimization.

5.12.4 C++

RTTI (3.19.1 on page 564)-data may be also useful for C++ class identification.

31 https://github.com/weidai11/cryptopp/blob/b613522794a7633aaa2bd81932a98a0b0a51bc04f/twofish.cpp

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
5.12.5 Crash on purpose

Often you need to know, which function has been executed, and which is not. You can use a debugger, but on exotic architectures there may not be the one, so easiest way is to put there an invalid opcode, or something like INT3 (0xCC). The crash would signal about the very fact this instruction has been executed.

Another example of crashing on purpose: 3.21.4 on page 613.
Chapter 6

OS-specific

6.1 Arguments passing methods (calling conventions)

6.1.1 cdecl

This is the most popular method for passing arguments to functions in the C/C++ languages. The glscaller also must return the value of the stack pointer (ESP) to its initial state after the callee function exits.

Listing 6.1: cdecl

```c
push arg3
push arg2
push arg1
 call function
add esp, 12 ; returns ESP
```

6.1.2 stdcall

It’s almost the same as cdecl, with the exception that the callee must set ESP to the initial state by executing the RET x instruction instead of RET, where x = arguments number * sizeof(int)\(^1\). The caller is not adjusting the stack pointer, there are no add esp, x instruction.

Listing 6.2: stdcall

```c
push arg3
push arg2
push arg1
 call function

function:
... do something ...
ret 12
```

The method is ubiquitous in win32 standard libraries, but not in win64 (see below about win64). For example, we can take the function from 1.89 on page 97 and change it slightly by adding the __stdcall modifier:

```c
int __stdcall f2 (int a, int b, int c)
{
    return a*b+c;
};
```

It is to be compiled in almost the same way as 1.90 on page 97, but you will see RET 12 instead of RET. SP is not updated in the caller.

\(^1\)The size of an int type variable is 4 in x86 systems and 8 in x64 systems
As a consequence, the number of function arguments can be easily deduced from the RETN $n$ instruction: just divide $n$ by 4.

Listing 6.3: MSVC 2010

```asm
    _a$ = 8   ; size = 4
    _b$ = 12  ; size = 4
    _c$ = 16  ; size = 4
    __f2@12 PROC
        push    ebp
        mov     ebp, esp
        mov eax, DWORD PTR _a$[ebp]
        imul eax, DWORD PTR _b$[ebp]
        add eax, DWORD PTR _c$[ebp]
        pop ebp
        ret 12
    __f2@12 ENDP

    ; ...
    push 3
    push 2
    push 1
    call __f2@12
    push eax
    push OFFSET $SG81369
    call __printf
    add esp, 8
```

Functions with variable number of arguments

`printf()`-like functions are, probably, the only case of functions with a variable number of arguments in C/C++, but it is easy to illustrate an important difference between cdecl and stdcall with their help. Let’s start with the idea that the compiler knows the argument count of each `printf()` function call.

However, the called `printf()`, which is already compiled and located in MSVCRT.DLL (if we talk about Windows), does not have any information about how much arguments were passed, however it can determine it from the format string.

Thus, if `printf()` would be a stdcall function and restored stack pointer to its initial state by counting the number of arguments in the format string, this could be a dangerous situation, when one programmer’s typo can provoke a sudden program crash. Thus it is not suitable for such functions to use stdcall, cdecl is better.

6.1.3fastcall

That’s the general naming for the method of passing some arguments via registers and the rest via the stack. It worked faster than cdecl/stdcall on older CPUs (because of smaller stack pressure). It may not help to gain any significant performance on latest (much more complex) CPUs, however.

It is not standardized, so the various compilers can do it differently. It’s a well known caveat: if you have two DLLs and the one uses another one, and they are built by different compilers with differentfastcall calling conventions, you can expect problems.

Both MSVC and GCC pass the first and second arguments via ECX and EDX and the rest of the arguments via the stack.

The stack pointer must be restored to its initial state by the callee (like in stdcall).

Listing 6.4:fastcall

```asm
    push arg3
    mov edx, arg2
    mov ecx, arg1
    call function

    function:
    .. do something ..
    ret 4
```
For example, we may take the function from 1.89 on page 97 and change it slightly by adding a __fastcall modifier:

```c
int __fastcall f3 (int a, int b, int c)
{
    return a*b+c;
};
```

Here is how it is to be compiled:

```c
Listing 6.5: Optimizing MSVC 2010 /Ob0

_c$ = 8 ; size = 4
@f3@12 PROC ;_a$ = ecx ;_b$ = edx
           mov eax, ecx
           imul eax, edx
           add eax, DWORD PTR _c$[esp-4]
ret 4
@f3@12 ENDP

; ... 
           mov edx, 2
           push 3
           lea ecx, DWORD PTR [edx-1]
call @f3@12
           push eax
           push OFFSET $SG81390
call __printf
           add esp, 8
```

We see that the callee returns SP by using the RETN instruction with an operand. Which implies that the number of arguments can be deduced easily here as well.

**GCC regparm**

It is the evolution offastcall\(^2\) in some sense. With the -mregparm option it is possible to set how many arguments are to be passed via registers (3 is the maximum). Thus, the EAX, EDX and ECX registers are to be used.

Of course, if the number the of arguments is less than 3, not all 3 registers are to be used.

The caller restores the stack pointer to its initial state.

For example, see (1.28.1 on page 309).

**Watcom/OpenWatcom**

Here it is called “register calling convention”. The first 4 arguments are passed via the EAX, EDX, EBX and ECX registers. All the rest—via the stack.

These functions have an underscore appended to the function name in order to distinguish them from those having a different calling convention.

**6.1.4 thiscall**

This is passing the object’s this pointer to the function-method, in C++.

In MSVC, this is usually passed in the ECX register.

In GCC, the this pointer is passed as the first function-method argument. Thus it will be visible that all functions in assembly code have an extra argument, in comparison with the source code.

For an example, see (3.19.1 on page 549).

\(^2\)http://go.yurichev.com/17040

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The method of for passing arguments in Win64 somewhat resembles fastcall. The first 4 arguments are passed via RCX, RDX, R8 and R9, the rest—via the stack. The caller also must prepare space for 32 bytes or 4 64-bit values, so then the callee can save there the first 4 arguments. Short functions may use the arguments’ values just from the registers, but larger ones may save their values for further use.

The caller also must return the stack pointer into its initial state.

This calling convention is also used in Windows x86-64 system DLLs (instead of stdcall in win32).

Example:

```c
#include <stdio.h>

void f1(int a, int b, int c, int d, int e, int f, int g)
{
    printf("%d %d %d %d %d %d\n", a, b, c, d, e, f, g);
};

int main()
{
    f1(1,2,3,4,5,6,7);
};
```

Listing 6.6: MSVC 2012 /0b

```asm
$SG2937 DB `\%d %d %d %d %d %d', 0aH, 00H

main PROC
sub    rsp, 72
    mov   DWORD PTR [rsp+48], 7
    mov   DWORD PTR [rsp+48], 6
    mov   DWORD PTR [rsp+32], 5
    mov   r9d, 4
    mov   r8d, 3
    mov   edx, 2
    mov   ecx, 1
    call  f1
    xor   eax, eax
    add   rsp, 72
    ret   0
main ENDP

a$ = 80
b$ = 88
c$ = 96
d$ = 104
e$ = 112
f$ = 120
g$ = 128
f1 PROC
$LN3:
    mov   DWORD PTR [rsp+32], r9d
    mov   DWORD PTR [rsp+24], r8d
    mov   DWORD PTR [rsp+16], edx
    mov   DWORD PTR [rsp+8], ecx
    sub   rsp, 72
    mov   eax, DWORD PTR g$[rsp]
    mov   DWORD PTR [rsp+56], eax
    mov   eax, DWORD PTR f$[rsp]
    mov   DWORD PTR [rsp+48], eax
    mov   eax, DWORD PTR e$[rsp]
    mov   DWORD PTR [rsp+40], eax
    mov   eax, DWORD PTR d$[rsp]
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here we clearly see how 7 arguments are passed: 4 via registers and the remaining 3 via the stack.

The code of the f1() function’s prologue saves the arguments in the “scratch space”—a space in the stack intended exactly for this purpose.

This is arranged so because the compiler cannot be sure that there will be enough registers to use without these 4, which will otherwise be occupied by the arguments until the function’s execution end.

The “scratch space” allocation in the stack is the caller’s duty.

Listing 6.7: Optimizing MSVC 2012 /0b

```
$SG2777 DB '%%d %%d %%d %%d %%d', 0AH, 00H
a$ = 80
b$ = 88
c$ = 96
d$ = 104
e$ = 112
f$ = 120
g$ = 128
f1 PROC
$LN3:
sub rsb, 72
mov eax, DWORD PTR g$[rsp]
mov DWORD PTR [rsp+56], eax
mov eax, DWORD PTR f$[rsp]
mov DWORD PTR [rsp+48], eax
mov eax, DWORD PTR e$[rsp]
mov DWORD PTR [rsp+48], eax
mov DWORD PTR [rsp+48], eax
mov r9d, r8d
mov r8d, edx
mov edx, ecx
lea rcx, OFFSET FLAT:$SG2777
call printf
add rsb, 72
ret 0
f1 ENDP
main PROC
sub rsb, 72
mov edx, 2
mov DWORD PTR [rsp+48], 7
mov DWORD PTR [rsp+40], 6
lea r9d, QWORD PTR [rdx+2]
lea r8d, QWORD PTR [rdx+1]
lea ecx, QWORD PTR [rdx-1]
mov DWORD PTR [rsp+32], 5
call f1
xor eax, eax
add rsb, 72
ret 0
main ENDP
```

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
If we compile the example with optimizations, it is to be almost the same, but the “scratch space” will not be used, because it won’t be needed.

Also take a look on how MSVC 2012 optimizes the loading of primitive values into registers by using LEA (.1.6 on page 1001). MOV would be 1 byte longer here (5 instead of 4).

Another example of such thing is: 8.1.1 on page 797.

**Windows x64: Passing this (C/C++)**

The this pointer is passed in RCX, the first argument of the method is in RDX, etc. For an example see: 3.19.1 on page 551.

**Linux x64**

The way arguments are passed in Linux for x86-64 is almost the same as in Windows, but 6 registers are used instead of 4 (RDI, RSI, RDX, RCX, R8, R9) and there is no “scratch space”, although the callee may save the register values in the stack, if it needs/wants to.

Listing 6.8: Optimizing GCC 4.7.3

```
.LC0:
    .string "%d %d %d %d %d\n"
f1:
    sub  rbp, 40
    mov  eax, DWORD PTR [rbp+48]
    mov  DWORD PTR [rbp+8], r9d
    mov  r9d, ecx
    mov  DWORD PTR [rbp], r8d
    mov  ecx, esi
    mov  r8d, edx
    mov  esi, OFFSET FLAT:.LC0
    mov  edx, edi
    mov  edi, 1
    mov  DWORD PTR [rbp+16], eax
    xor  eax, eax
    call __printf_chk
    add  rbp, 40
    ret

main:
    sub  rbp, 24
    mov  r9d, 6
    mov  r8d, 5
    mov  DWORD PTR [rbp], 7
    mov  ecx, 4
    mov  edx, 3
    mov  esi, 2
    mov  edi, 1
    call f1
    add  rbp, 24
    ret
```

N.B.: here the values are written into the 32-bit parts of the registers (e.g., EAX) but not in the whole 64-bit register (RAX). This is because each write to the low 32-bit part of a register automatically clears the high 32 bits. Supposedly, it was decided in AMD to do so to simplify porting code to x86-64.

### 6.1.6 Return values of float and double type

In all conventions except in Win64, the values of type float or double are returned via the FPU register ST(0).

In Win64, the values of float and double types are returned in the low 32 or 64 bits of the XMM0 register.
6.1.7 Modifying arguments

Sometimes, C/C++ programmers (not limited to these PLs, though), may ask, what can happen if they modify the arguments?

The answer is simple: the arguments are stored in the stack, that is where the modification takes place. The calling functions is not using them after the callee’s exit (the author of these lines has never seen any such case in his practice).

```c
#include <stdio.h>

void f(int a, int b)
{
    a=a+b;
    printf ("%d\n", a);
}

Listing 6.9: MSVC 2012

_a$ = 8 ; size = 4
_b$ = 12 ; size = 4

_f PROC
    push ebp
    mov ebp, esp
    mov eax, DWORD PTR _a$[ebp]
    add eax, DWORD PTR _b$[ebp]
    mov DWORD PTR _a$[ebp], eax
    mov ecx, DWORD PTR _a$[ebp]
    push ecx
    push OFFSET $SG2938 ; '%d', 0aH
    call _printf
    add esp, 8
    pop esp
    ret 0
_f ENDP
```

So yes, one can modify the arguments easily. Of course, if it is not references in C++ (3.19.3 on page 565), and if you don’t modify data to which a pointer points to, then the effect will not propagate outside the current function.

Theoretically, after the callee’s return, the caller could get the modified argument and use it somehow. Maybe if it is written directly in assembly language.

For example, code like this will be generated by usual C/C++ compiler:

```assembly
push 456 ; will be b
push 123 ; will be a
call f ; f() modifies its first argument
add esp, 2*4
```

We can rewrite this code like:

```assembly
push 456 ; will be b
push 123 ; will be a
call f ; f() modifies its first argument
pop eax
add esp, 4 ; EAX=1st argument of f() modified in f()
```

Hard to imagine, why anyone would need this, but this is possible in practice. Nevertheless, the C/C++ languages standards don’t offer any way to do so.

6.1.8 Taking a pointer to function argument

...even more than that, it’s possible to take a pointer to the function’s argument and pass it to another function:

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
#include <stdio.h>

// located in some other file
void modify_a (int *a);

void f (int a)
{
    modify_a (&a);
    printf ("%d\n", a);
};

It's hard to understand how it works until we can see the code:

Listing 6.10: Optimizing MSVC 2010

SG2796 DB '%d', 0aH, 00H

_a$ = 8
_f PROC
    lea   eax, DWORD PTR _a$[esp-4] ; just get the address of value in local stack
    push  eax
    call  _modify_a
    mov  ecx, DWORD PTR _a$[esp]  ; reload it from the local stack
    push  ecx
    push  OFFSET $SG2796
    call  _printf
    add   esp, 12
    ret 0
_f ENDP

The address of the place in the stack where \texttt{a} has been passed is just passed to another function. It modifies the value addressed by the pointer and then \texttt{printf()} prints the modified value.

The observant reader might ask, what about calling conventions where the function's arguments are passed in registers?

That's a situation where the \textit{Shadow Space} is used.

The input value is copied from the register to the \textit{Shadow Space} in the local stack, and then this address is passed to the other function:

Listing 6.11: Optimizing MSVC 2012 x64

SG2994 DB '%d', 0aH, 00H

a$ = 48
_f PROC
    mov  DWORD PTR [rsp+8], ecx  ; save input value in Shadow Space
    sub  rsp, 40
    lea   rcx, QWORD PTR a$[rsp] ; get address of value and pass it to modify_a()
    call  modify_a
    mov  edx, DWORD PTR a$[rsp] ; reload value from Shadow Space and pass it to
    call  _modify_a
    mov  rdx, OFFSET FLAT:$SG2994 ; '%d'
    call  printf
    add   esp, 40
    ret 0
_f ENDP

GCC also stores the input value in the local stack:

Listing 6.12: Optimizing GCC 4.9.1 x64

.LC0:
    .string "%d\n"
_f:
    sub    rsp, 24
    mov    DWORD PTR [rsp+12], edi ; store input value to the local stack
    lea    rdi, [rsp+12]
    call   modify_a
    call   modify_a

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
GCC for ARM64 does the same, but this space is called Register Save Area here:

```
Listing 6.13: Optimizing GCC 4.9.1 ARM64

f:
    stp    x29, x30, [sp, -32]!  ; setup FP
    add    x29, sp, 0
    add    x1, x29, 32           ; calculate address of variable in Register Save Area
    str    w0, [x1, -4]!         ; store input value there
    mov    x0, x1                ; pass address of variable to the modify_a()
    bl     modify_a
    ldr    w1, [x29, 28]         ; load value from the variable and pass it to printf()
    adrp   x0, .LC0              ; '%d'
    add    x0, x0, :lo12:.LC0    ; call printf()
    bl     printf
    ldp    x29, x30, [sp], 32
    ret

.LC0:
    .string "%d\n"
```

By the way, a similar usage of the Shadow Space is also considered here: 3.15.1 on page 527.

### 6.1.9 Python ctypes problem (x86 assembly homework)

A Python ctypes module can call external functions in DLLs, .so’s, etc. But calling convention (for 32-bit environment) must be specified explicitly:

"ctypes" exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects.
*cdll* loads libraries which export functions using the standard "cdecl" calling convention, while *windll* libraries call functions using the "stdcall" calling convention.

([https://docs.python.org/3/library/ctypes.html](https://docs.python.org/3/library/ctypes.html))

In fact, we can modify ctypes module (or any other caller code), so that it will successfully call external cdecl or stdcall functions, without knowledge, which is where. (Number of arguments, however, is to be specified).

This is possible to solve using maybe 5-10 x86 assembly instructions in caller. Try to find out these.

### 6.2 Thread Local Storage

TLS is a data area, specific to each thread. Every thread can store what it needs there. One well-known example is the C standard global variable `errno`.

Multiple threads may simultaneously call functions which return an error code in `errno`, so a global variable will not work correctly here for multi-threaded programs, so `errno` must be stored in the TLS.

In the C++11 standard, a new `thread_local` modifier was added, showing that each thread has its own version of the variable, it can be initialized, and it is located in the TLS.

---

3 C11 also has thread support, optional though
#include <iostream>
#include <thread>

thread_local int tmp=3;

int main()
{
    std::cout << tmp << std::endl;
}

Compiled in MinGW GCC 4.8.1, but not in MSVC 2012.

If we talk about PE files, in the resulting executable file, the tmp variable is to be allocated in the section devoted to the TLS.

## 6.2.1 Linear congruential generator revisited

The pseudorandom number generator we considered earlier 1.29 on page 341 has a flaw: it's not thread-safe, because it has an internal state variable which can be read and/or modified in different threads simultaneously.

### Win32

**Uninitialized TLS data**

One solution is to add `__declspec( thread )` modifier to the global variable, then it will be allocated in the TLS (line 9):

```c
#include <stdint.h>
#include <windows.h>
#include <winnt.h>

// from the Numerical Recipes book:
#define RNG_a 1664525
#define RNG_c 1013904223
__declspec(thread) uint32_t rand_state;

void my_srand (uint32_t init)
{
    rand_state=init;
}

int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state+RNG_c;
    return rand_state & 0x7fff;
}

int main()
{
    my_srand(0x12345678);
    printf ("%d\n", my_rand());
}
```

Hiew shows us that there is a new PE section in the executable file: .tls.

### Optimizing MSVC 2013 x86

```
_TLS SEGMENT
_rand_state DD 01H DUP (?)
_TLS ENDS
_DATA SEGMENT
```
rand_state is now in the TLS segment, and each thread has its own version of this variable. Here is how it's accessed: load the address of the TIB from FS:2Ch, then add an additional index (if needed), then calculate the address of the TLS segment.

Then it's possible to access the rand_state variable through the ECX register, which points to an unique area in each thread.

The FS: selector is familiar to every reverse engineer, it is specially used to always point to TIB, so it would be fast to load the thread-specific data.

The GS: selector is used in Win64 and the address of the TLS is 0x58:

Listing 6.16: Optimizing MSVC 2013 x64
Initialized TLS data

Let's say, we want to set some fixed value to rand_state, so in case the programmer forgets to, the rand_state variable would be initialized to some constant anyway (line 9):

```
#include <stdint.h>
#include <windows.h>
#include <winnt.h>

// from the Numerical Recipes book:
#define RNG_a 1664525
#define RNG_c 1013904223
__declspec(thread) uint32_t rand_state=1234;
void my_srand (uint32_t init)
{
    rand_state=init;
}

int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state+RNG_c;
    return rand_state & 0x7fff;
}

int main()
{
    printf ("%d\n", my_rand());
}
```

The code is not different from what we already saw, but in IDA we see:

```
<table>
<thead>
<tr>
<th>TLS Offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00404000</td>
<td>Segment type: Pure data</td>
</tr>
<tr>
<td>00404000</td>
<td>Segment permissions: Read/Write</td>
</tr>
<tr>
<td>00404000</td>
<td>TLS segment public 'DATA' use32</td>
</tr>
<tr>
<td>00404000</td>
<td>assume cs: tls</td>
</tr>
<tr>
<td>00404000</td>
<td>.org 404000h</td>
</tr>
<tr>
<td>00404000</td>
<td>TlsStart db 0 ; DATA XREF: .rdata:TlsDirectory</td>
</tr>
<tr>
<td>00404001</td>
<td>db 0</td>
</tr>
<tr>
<td>00404002</td>
<td>db 0</td>
</tr>
<tr>
<td>00404003</td>
<td>db 0</td>
</tr>
<tr>
<td>00404004</td>
<td>dd 1234</td>
</tr>
<tr>
<td>00404008</td>
<td>TlsEnd db 0 ; DATA XREF: .rdata:TlsEnd_ptr</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

1234 is there and every time a new thread starts, a new TLS is allocated for it, and all this data, including 1234, will be copied there.

This is a typical scenario:

- Thread A is started. A TLS is created for it, 1234 is copied to rand_state.
- The my_rand() function is called several times in thread A. rand_state is different from 1234.
- Thread B is started. A TLS is created for it, 1234 is copied to rand_state, while thread A has a different value in the same variable.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
**TLS callbacks**

But what if the variables in the TLS have to be filled with some data that must be prepared in some unusual way?

Let's say, we've got the following task: the programmer can forget to call the `my_srand()` function to initialize the PRNG, but the generator has to be initialized at start with something truly random, instead of 1234. This is a case in which TLS callbacks can be used.

The following code is not very portable due to the hack, but nevertheless, you get the idea.

What we do here is define a function (`tls_callback()`) which is to be called before the process and/or thread start.

The function initializes the PRNG with the value returned by `GetTickCount()` function.

```c
#include <stdint.h>
#include <windows.h>
#include <winnt.h>

// from the Numerical Recipes book:
#define RNG_a 1664525
#define RNG_c 1013904223
__declspec(thread) uint32_t rand_state;

void my_srand (uint32_t init)
{
    rand_state = init;
}

void NTAPI tls_callback(PVOID a, DWORD dwReason, PVOID b)
{
    my_srand(GetTickCount());
}

#pragma data_seg(".CRT$XLB")
PIMAGE_TLS_CALLBACK p_thread_callback = tls_callback;
#pragma data_seg()

int my_rand()
{
    rand_state = rand_state * RNG_a;
    rand_state = rand_state + RNG_c;
    return rand_state & 0x7fff;
}

int main()
{
    // rand_state is already initialized at the moment (using GetTickCount())
    printf("%d\n", my_rand());
}
```

Let's see it in IDA:

**Listing 6.17: Optimizing MSVC 2013**

```
.text:00401020 TlsCallback_0 proc near ; DATA XREF: .rdata:TlsCallbacks
.text:00401020 call ds:GetTickCount
.text:00401026 push eax
.text:00401027 call my_srand
.text:0040102C pop ecx
.text:0040102D retn 0Ch
.text:0040102D TlsCallback_0 endp

... .rdata:004020C0 TlsCallbacks dd offset TlsCallback_0 ; DATA XREF: .rdata:TlsCallbacks_ptr
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
TLS callback functions are sometimes used in unpacking routines to obscure their processing. Some people may be confused and be in the dark that some code executed right before the OEP\(^4\).

**Linux**

Here is how a thread-local global variable is declared in GCC:

```c
__thread uint32_t rand_state=1234;
```

This is not the standard C/C++ modifier, but a rather GCC-specific one\(^5\).

The GS: selector is also used to access the TLS, but in a somewhat different way:

Listing 6.18: Optimizing GCC 4.8.1 x86

```assembly
.text:00048460 my_srand proc near
.text:00048460 .text:00048460 arg_0 = dword ptr 4
.text:00048460 .text:00048460 mov eax, [esp+arg_0]
.text:0004846A .text:0004846A my_srand retn

```

More about it: [Ulrich Drepper, *ELF Handling For Thread-Local Storage*, (2013)]\(^6\).

### 6.3 System calls (syscall-s)

As we know, all running processes inside an OS are divided into two categories: those having full access to the hardware (“kernel space”) and those that do not (“user space”).

The OS kernel and usually the drivers are in the first category.

All applications are usually in the second category.

For example, Linux kernel is in *kernel space*, but Glibc in *user space*.

This separation is crucial for the safety of the OS: it is very important not to give to any process the possibility to screw up something in other processes or even in the OS kernel. On the other hand, a failing driver or error inside the OS’s kernel usually leads to a kernel panic or BSOD\(^7\).

The protection in the x86 processors allows to separate everything into 4 levels of protection (rings), but both in Linux and in Windows only two are used: ring0 (“kernel space”) and ring3 (“user space”).

System calls (syscall-s) are a point where these two areas are connected.

It can be said that this is the main API provided to applications.

As in Windows NT, the syscalls table resides in the SSDT®.

The usage of syscalls is very popular among shellcode and computer viruses authors, because it is hard to determine the addresses of needed functions in the system libraries, but it is easier to use syscalls. However, much more code has to be written due to the lower level of abstraction of the API.

It is also worth noting that the syscall numbers may be different in various OS versions.

### 6.3.1 Linux

In Linux, a syscall is usually called via int 0x80. The call’s number is passed in the EAX register, and any other parameters — in the other registers.

Listing 6.19: A simple example of the usage of two syscalls

```assembly
section .text
section .data

.global _start

_start:
    mov edx, len ; buffer len
    mov ecx, msg ; buffer
    mov ebx, 1 ; file descriptor. 1 is for stdout
    mov eax, 4 ; syscall number. 4 is for sys_write
    int 0x80
    mov eax, 1 ; syscall number. 1 is for sys_exit
    int 0x80

msg db 'Hello, world!', 0xa
len equ $ - msg
```

Compilation:

```
nasm -f elf32 1.s
ld 1.o
```

The full list of syscalls in Linux: [http://go.yurichev.com/17319](http://go.yurichev.com/17319).

For system calls interception and tracing in Linux, strace( 7.2.3 on page 791) can be used.

### 6.3.2 Windows

Here they are called via int 0x2e or using the special x86 instruction SYSENTER.

Further reading:

### 6.4 Linux

#### 6.4.1 Position-independent code

While analyzing Linux shared (.so) libraries, one may frequently spot this code pattern:

Listing 6.20: libc-2.17.so x86

```assembly
.text:0012D5E3 __x86_get_pc_thunk_bx proc near ; CODE XREF: sub_17350+3
.text:0012D5E3 mov ebx, [esp+0] ; sub_173CC+4 ...
.text:0012D5E6 ret
```

8System Service Dispatch Table

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
All pointers to strings are corrected by some constants and the value in EBX, which is calculated at the beginning of each function.

This is the so-called PIC, it is intended to be executable if placed at any random point of memory, that is why it cannot contain any absolute memory addresses.

PIC was crucial in early computer systems and is still crucial today in embedded systems without virtual memory support (where all processes are placed in a single continuous memory block).

It is also still used in *NIX systems for shared libraries, since they are shared across many processes while loaded in memory only once. But all these processes can map the same shared library at different addresses, so that is why a shared library has to work correctly without using any absolute addresses.

Let's do a simple experiment:

```c
#include <stdio.h>

int global_variable = 123;

int f1(int var)
{
    int rt = global_variable + var;
    printf("returning \%d\n", rt);
    return rt;
}
```

Let's compile it in GCC 4.7.3 and see the resulting .so file in IDA:

```
gcc -fPIC -shared -O3 -o 1.so 1.c
```

Listing 6.21: GCC 4.7.3
That's it: the pointers to «returning %d\n» and global_variable are to be corrected at each function execution.

The __x86_get_pc_thunk_bx() function returns in EBX the address of the point after a call to itself (0x57C here).

That's a simple way to get the value of the program counter (EIP) at some point. The 0x1A84 constant is related to the difference between this function's start and the so-called Global Offset Table Procedure Linkage Table (GOT PLT), the section right after the Global Offset Table (GOT), where the pointer to global_variable is. IDA shows these offsets in their processed form to make them easier to understand, but in fact the code is:

```
.text:00000577    call __x86_get_pc_thunk_bx
.text:0000057C    add ebx, 1A84h
.text:00000582    mov [esp+1Ch+var_4], esi
.text:00000586    mov eax, ds:(global_variable_ptr - 2000h)[ebx]
.text:0000058C    mov esi, [eax]
.text:0000058E    lea eax, (aReturningD - 2000h)[ebx]; "returning %d\n"
.text:00000594    add esi, [esp+1Ch+arg_0]
.text:00000598    mov [esp+1Ch+var_18], eax
.text:0000059C    mov [esp+1Ch+var_1C], 1
.text:000005A3    mov [esp+1Ch+var_14], esi
.text:000005A7    call __printf_chk
.text:000005AC    mov eax, esi
.text:000005AE    mov ebx, [esp+1Ch+var_8]
.text:000005B2    mov esi, [esp+1Ch+var_4]
.text:000005B6    add esp, 1Ch
.text:000005B9    ret
.text:000005B9 f1    endp
```

Here EBX points to the GOT PLT section and to calculate a pointer to global_variable (which is stored in the GOT), 0xC must be subtracted.

To calculate pointer to the «returning %d\n» string, 0x1A30 must be subtracted.

By the way, that is the reason why the AMD64 instruction set supports RIP\(^9\)-relative addressing — to simplify PIC-code.

Let's compile the same C code using the same GCC version, but for x64.

IDA would simplify the resulting code but would suppress the RIP-relative addressing details, so we are going to use objdump instead of IDA to see everything:

```
0000000000007200 <f1>:  
720:  48 8b 05 b9 8b 20 00     mov    rax,QWORD PTR [rip+0x208b9]  
200fe0 <DYNAMIC+0x1d0>  
727:  53                   push   rbx
728:  89 fb                mov    ebx,edi
72a:  48 8d 35 20 00 00 00  lea    rsi,[rip+0x20]  ; 751 <__fini+0x9>
731:  bf 01 00 00 00 00     mov    edi,0x1
736:  63 18                add    ebx,QWORD PTR [rax]
738:  31 c0                xor    eax,eax
73a:  89 da                mov    edx,ebx
```

\(^9\)program counter in AMD64

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
0x2008b9 is the difference between the address of the instruction at 0x720 and global_variable, and 0x20 is the difference between the address of the instruction at 0x72A and the «returning %d\n» string.

As you might see, the need to recalculate addresses frequently makes execution slower (it is better in x64, though).

So it is probably better to link statically if you care about performance [see: Agner Fog, Optimizing software in C++ (2015)].

Windows

The PIC mechanism is not used in Windows DLLs. If the Windows loader needs to load DLL on another base address, it “patches” the DLL in memory (at the FIXUP places) in order to correct all addresses.

This implies that several Windows processes cannot share an once loaded DLL at different addresses in different process’ memory blocks — since each instance that’s loaded in memory is fixed to work only at these addresses..

6.4.2 LD_PRELOAD hack in Linux

This allows us to load our own dynamic libraries before others, even before system ones, like libc.so.6.

This, in turn, allows us to “substitute” our written functions before the original ones in the system libraries. For example, it is easy to intercept all calls to time(), read(), write(), etc.

Let’s see if we can fool the uptime utility. As we know, it tells how long the computer has been working. With the help of strace(7.2.3 on page 791), it is possible to see that the utility takes this information the /proc/uptime file:

```
$ strace uptime
...
open("/proc/uptime", O_RDONLY) = 3
lseek(3, 0, SEEK_SET) = 0
read(3, "416166.86 414629.38\n", 2047) = 20
...
```

It is not a real file on disk, it is a virtual one and its contents are generated on fly in the Linux kernel. There are just two numbers:

```
$ cat /proc/uptime
416690.91 415152.03
```

What we can learn from Wikipedia 10:

```
The first number is the total number of seconds the system has been up. The second number is how much of that time the machine has spent idle, in seconds.
```

Let’s try to write our own dynamic library with the open(), read(), close() functions working as we need. At first, our open() will compare the name of the file to be opened with what we need and if it is so, it will write down the descriptor of the file opened.

Second, read(), if called for this file descriptor, will substitute the output, and in the rest of the cases will call the original read() from libc.so.6. And also close(), will note if the file we are currently following is to be closed.

We are going to use the dlopen() and dlsym() functions to determine the original function addresses in libc.so.6.

10wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We need them because we must pass control to the “real” functions.

On the other hand, if we intercepted strcmp() and monitored each string comparisons in the program, then we would have to implement our version of strcmp(), and not use the original function \(^{11}\), that would be easier.

```c
#include <stdio.h>
#include <stdarg.h>
#include <stdlib.h>
#include <stdbool.h>
#include <unistd.h>
#include <dlfcn.h>
#include <string.h>

void *libc_handle = NULL;
int (*open_ptr)(const char *, int) = NULL;
int (*close_ptr)(int) = NULL;
ssize_t (*read_ptr)(int, void*, size_t) = NULL;

bool inited = false;

_Noreturn void die (const char * fmt, ...)
{
    va_list va;
    va_start (va, fmt);
    vprintf (fmt, va);
    exit(0);
}

static void find_original_functions ()
{
    if (inited)
        return;

    libc_handle = dlopen("libc.so.6", RTLD_LAZY);
    if (libc_handle==NULL)
        die ("can't open libc.so.6\n");

    open_ptr = dlsym (libc_handle, "open");
    if (open_ptr==NULL)
        die ("can't find open()\n");

    close_ptr = dlsym (libc_handle, "close");
    if (close_ptr==NULL)
        die ("can't find close()\n");

    read_ptr = dlsym (libc_handle, "read");
    if (read_ptr==NULL)
        die ("can't find read()\n");

    inited = true;
}

static int opened_fd=0;

int open(const char *pathname, int flags)
{
    find_original_functions();

    int fd=(*open_ptr)(pathname, flags);
    if (strcmp(pathname, "/proc/uptime")==0)
        opened_fd=fd; // that's our file! record its file descriptor
    else
        opened_fd=0;
    return fd;
}

int close(int fd)
```

\(^{11}\)For example, here is how simple strcmp() interception works in this article \(^{12}\) written by Yong Huang

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's compile it as common dynamic library:

```bash
gcc -fpic -shared -Wall -o fool_uptime.so fool_uptime.c -ldl
```

Let's run `uptime` while loading our library before the others:

```bash
LD_PRELOAD=`pwd`/fool_uptime.so uptime
```

And we see:

```
01:23:02 up 24855 days, 3:14, 3 users, load average: 0.00, 0.01, 0.05
```

If the `LD_PRELOAD` environment variable always points to the filename and path of our library, it is to be loaded for all starting programs.

More examples:

- Very simple interception of the `strcmp()` (Yong Huang) [http://go.yurichev.com/17143](http://go.yurichev.com/17143)
- Kevin Pulo—Fun with LD_PRELOAD. A lot of examples and ideas. [yurichev.com](http://go.yurichev.com/17146)

### 6.5 Windows NT

#### 6.5.1 CRT (win32)

Does the program execution start right at the `main()` function? No, it does not.

If we would open any executable file in IDA or HIEW, we can see OEP pointing to some another code block. This code is doing some maintenance and preparations before passing control flow to our code. It is called startup-code or CRT code (C RunTime).

The `main()` function takes an array of the arguments passed on the command line, and also one with environment variables. But in fact a generic string is passed to the program, the CRT code finds the spaces in it and cuts it in parts. The CRT code also prepares the environment variables array `envp`.

As for GUI\(^\text{13}\) win32 applications, `WinMain` is used instead of `main()`, having its own arguments:

13\(^{\text{Graphical User Interface}}\)
int CALLBACK WinMain(  
    _In_ HINSTANCE hInstance,  
    _In_ HINSTANCE hPrevInstance,  
    _In_ LPSTR lpCmdLine,  
    _In_ int nCmdShow  
);  

The CRT code prepares them as well.  
Also, the number returned by the main() function is the exit code.  
It may be passed in CRT to the ExitProcess() function, which takes the exit code as an argument.  

Usually, each compiler has its own CRT code.  

Here is a typical CRT code for MSVC 2008.

---

(The CRT code prepares them as well.)

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
call __ioinit

test eax, eax
jge short loc_4010D9
push 1Bh
call __amsg_exit
pop ecx

loc_4010D9: ; CODE XREF: ___tmainCRTStartup+8B

call ds:GetCommandLineA
mov dword_40B7F8, eax
call __crtGetEnvironmentStringsA
mov dword_40AC60, eax
call __setargv

_jge eax, eax
loc_4010F9: ; CODE XREF: ___tmainCRTStartup+81

call __amsg_exit

loc_401110: ; CODE XREF: ___tmainCRTStartup+C2
push 1
call __cinit
pop ecx
test eax, eax
jz short loc_401123
push eax
call __amsg_exit
pop ecx

loc_401123: ; CODE XREF: ___tmainCRTStartup+D6
mov eax, envp
mov dword_40AC80, eax
push eax ; envp
push argv ; argv
push argc ; argc
call __main
add esp, 0Ch
mov [ebp+var_28], eax
cmp [ebp+var_1C], 0
jnz short $LN28
push eax ; uExitCode
call $LN32

$LN28: ; CODE XREF: ___tmainCRTStartup+105

call __exit
jmp short loc_401186

$LN27: ; DATA XREF: .rdata:stru_4092D0

mov eax, [ebp+ms_exc.exc_ptr] ; Exception filter 0 for function 401044
mov ecx, [eax]
mov ecx, [ecx]

$LN24:

ret
Here we can see calls to GetCommandLineA() (line 62), then to setargv() (line 66) and setenvp() (line 74), which apparently fill the global variables argc, argv, envp.

Finally, main() is called with these arguments (line 97).

There are also calls to functions with self-describing names like heap_init() (line 35), ioinit() (line 54). The heap is indeed initialized in the CRT. If you try to use malloc() in a program without CRT, it will exit abnormally with the following error:

Runtime error R6030
- CRT not initialized

Global object initializations in C++ is also occur in the CRT before the execution of main(): 3.19.4 on page 571.

The value that main() returns is passed to cexit(), or in $LN32, which in turn calls doexit().

Is it possible to get rid of the CRT? Yes, if you know what you are doing.

The MSVC’s linker has the /ENTRY option for setting an entry point.

```c
#include <windows.h>
int main()
{
    MessageBox(NULL, "hello, world", "caption", MB_OK);
}
```

Let’s compile it in MSVC 2008.

```
cl no_crt.c user32.lib /link /entry:main
```

We are getting a runnable .exe with size 2560 bytes, that has a PE header in it, instructions calling MessageBox, two strings in the data segment, the MessageBox function imported from user32.dll and nothing else.

This works, but you cannot write WinMain with its 4 arguments instead of main().

To be precise, you can, but the arguments are not prepared at the moment of execution.

By the way, it is possible to make the .exe even shorter by aligning the PE sections at less than the default 4096 bytes.

```
cl no_crt.c user32.lib /link /entry:main /align:16
```

Linker says:

```
LINK : warning LNK4108: /ALIGN specified without /DRIVER; image may not run
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
We get an .exe that’s 720 bytes. It can be executed in Windows 7 x86, but not in x64 (an error message will be shown when you try to execute it).

With even more efforts, it is possible to make the executable even shorter, but as you can see, compatibility problems arise quickly.

### 6.5.2 Win32 PE

PE is an executable file format used in Windows. The difference between .exe, .dll and .sys is that .exe and .sys usually do not have exports, only imports.

A DLL\(^{14}\), just like any other PE-file, has an entry point (OEP) (the function DllMain() is located there) but this function usually does nothing. .sys is usually a device driver. As of drivers, Windows requires the checksum to be present in the PE file and for it to be correct\(^ {15}\).

Starting at Windows Vista, a driver’s files must also be signed with a digital signature. It will fail to load otherwise.

Every PE file begins with tiny DOS program that prints a message like “This program cannot be run in DOS mode.”—if you run this program in DOS or Windows 3.1 (OS-es which are not aware of the PE format), this message will be printed.

#### Terminology

- **Module**—a separate file, .exe or .dll.
- **Process**—a program loaded into memory and currently running. Commonly consists of one .exe file and bunch of .dll files.
- **Process memory**—the memory a process works with. Each process has its own. There usually are loaded modules, memory of the stack, heap(s), etc.
- **VA\(^ {16}\)**—an address which is to be used in program while runtime.
- **Base address (of module)**—the address within the process memory at which the module is to be loaded. OS loader may change it, if the base address is already occupied by another module just loaded before.
- **RVA\(^ {17}\)**—the VA-address minus the base address.

Many addresses in PE-file tables use RVA-addresses.

- **IAT\(^ {18}\)**—an array of addresses of imported symbols\(^ {19}\). Sometimes, the IMAGE_DIRECTORY_ENTRY_IAT data directory points at the IAT. It is worth noting that IDA (as of 6.1) may allocate a pseudo-section named .idata for IAT, even if the IAT is a part of another section!
- **INT\(^ {20}\)**—an array of names of symbols to be imported\(^ {21}\).

#### Base address

The problem is that several module authors can prepare DLL files for others to use and it is not possible to reach an agreement which addresses is to be assigned to whose modules.

So that is why if two necessary DLLs for a process have the same base address, one of them will be loaded at this base address, and the other—at some other free space in process memory, and each virtual addresses in the second DLL will be corrected.

With MSVC the linker often generates the .exe files with a base address of 0x400000\(^ {22}\), and with the code section starting at 0x401000. This means that the RVA of the start of the code section is 0x1000.

---

\(^{14}\)Dynamic-Link Library

\(^{15}\)For example, Hiew(7.1 on page 789) can calculate it

\(^{16}\)Virtual Address

\(^{17}\)Relative Virtual Address

\(^{18}\)Import Address Table

\(^{19}\)Matt Pietrek, *An In-Depth Look into the Win32 Portable Executable File Format*, (2002)

\(^{20}\)Import Name Table

\(^{22}\)The origin of this address choice is described here: MSDN

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
DLLs are often generated by MSVC’s linker with a base address of 0x10000000. There is also another reason to load modules at various base addresses, in this case random ones. It is ASLR.

A shellcode trying to get executed on a compromised system must call system functions, hence, know their addresses.

In older OS (in Windows NT line: before Windows Vista), system DLL (like kernel32.dll, user32.dll) were always loaded at known addresses, and if we also recall that their versions rarely changed, the addresses of functions were fixed and shellcode could call them directly.

In order to avoid this, the ASLR method loads your program and all modules it needs at random base addresses, different every time.

ASLR support is denoted in a PE file by setting the flag IMAGE_DLL_CHARACTERISTICS_DYNAMIC_BASE [see Mark Russinovich, Microsoft Windows Internals].

Subsystem

There is also a subsystem field, usually it is:

- native (.sys-driver),
- console (console application) or
- GUI (non-console).

OS version

A PE file also specifies the minimal Windows version it needs in order to be loadable. The table of version numbers stored in the PE file and corresponding Windows codenames is here. For example, MSVC 2005 compiles .exe files for running on Windows NT4 (version 4.00), but MSVC 2008 does not (the generated files have a version of 5.00, at least Windows 2000 is needed to run them).

MSVC 2012 generates .exe files of version 6.00 by default, targeting at least Windows Vista. However, by changing the compiler’s options, it is possible to force it to compile for Windows XP.

Sections

Division in sections, as it seems, is present in all executable file formats.

It is devised in order to separate code from data, and data—from constant data.

- Either the IMAGE_SCN_CNT_CODE or IMAGE_SCN_MEM_EXECUTE flags will be set on the code section—this is executable code.
- On data section—IMAGE_SCN_CNT_INITIALIZED_DATA, IMAGE_SCN_MEM_READ and IMAGE_SCN_MEM_WRITE flags.
- On an empty section with uninitialized data—IMAGE_SCN_CNT_UNINITIALIZED_DATA, IMAGE_SCN_MEM_READ and IMAGE_SCN_MEM_WRITE.
- On a constant data section (one that’s protected from writing), the flags IMAGE_SCN_CNT_INITIALIZED_DATA and IMAGE_SCN_MEM_READ can be set, but not IMAGE_SCN_MEM_WRITE. A process going to crash if it tries to write to this section.

Each section in PE-file may have a name, however, it is not very important. Often (but not always) the code section is named .text, the data section—.data, the constant data section —.rdata (readable data) (perhaps, .rdata means read-only-data). Other popular section names are:

23This can be changed by the /BASE linker option
24wikipedia
25Meaning, the module use Native API instead of Win32
26wikipedia
27MSDN
• .idata—imports section. IDA may create a pseudo-section named like this: 6.5.2 on page 756.
• .edata—exports section (rare)
• .pdata—section holding all information about exceptions in Windows NT for MIPS, IA64 and x64: 6.5.3 on page 783
• .reloc—relocs section
• .bss—uninitialized data (BSS)
• .tls—thread local storage (TLS)
• .rsrc—resources
• .CRT—may present in binary files compiled by ancient MSVC versions
PE file packers/encryptors often garble section names or replace the names with their own.
MSVC allows you to declare data in arbitrarily named section 28.
Some compilers and linkers can add a section with debugging symbols and other debugging information (MinGW for instance). However it is not so in latest versions of MSVC (separate PDB files are used there for this purpose).

That is how a PE section is described in the file:

```c
typedef struct _IMAGE_SECTION_HEADER {
  BYTE  Name[IMAGE_SIZEOF_SHORT_NAME];
  union {
    DWORD  VirtualAddress;
    DWORD  VirtualSize;
  } Misc;
  DWORD  VirtualAddress;
  DWORD  SizeOfRawData;
  DWORD  PointerToRawData;
  DWORD  PointerToRelocations;
  DWORD  PointerToLinenumbers;
  WORD   NumberOfRelocations;
  WORD   NumberOfLinenumbers;
  DWORD  Characteristics;
} IMAGE_SECTION_HEADER, *PIMAGE_SECTION_HEADER;
```

29

A word about terminology: PointerToRawData is called “Offset” in Hiew and VirtualAddress is called “RVA” there.

Data section

Data section in file can be smaller than in memory. For example, some variables can be initialized, some are not. Compiler and linker will collect them all into one section, but the first part of it is initialized and allocated in file, while another is absent in file (of course, to make it smaller). VirtualSize will be equal to the size of section in memory, and SizeOfRawData — to size of section in file.

IDA can show the border between initialized and not initialized parts like that:

```c
...  
data:10017FFA    db  0  
data:10017FFB    db  0  
data:10017FFC    db  0  
data:10017FFD    db  0  
data:10017FFE    db  0  
data:10017FFF    db  0  
data:10018000    db  ? ;  
data:10018001    db  ? ;  
data:10018002    db  ? ;  
data:10018003    db  ? ;
```

.data — read-only data section

Strings are usually located here (because they have const char* type), other variables marked as const, imported function names.
See also: 3.2 on page 474.

Relocations (relocs)

AKA FIXUP-s (at least in Hiew).

They are also present in almost all executable file formats. Exceptions are shared dynamic libraries compiled with PIC, or any other PIC-code.

What are they for?

Obviously, modules can be loaded on various base addresses, but how to deal with global variables, for example? They must be accessed by address. One solution is position-independent code (6.4.1 on page 747). But it is not always convenient.

That is why a relocations table is present. There the addresses of points that must be corrected are enumerated, in case of loading at a different base address.

For example, there is a global variable at address 0x410000 and this is how it is accessed:

```
A1 00 00 41 00 mov eax,[000410000]
```

The base address of the module is 0x400000, the RVA of the global variable is 0x10000.
If the module is loaded at base address 0x500000, the real address of the global variable must be 0x510000.
As we can see, the address of variable is encoded in the instruction MOV, after the byte 0xA1.
That is why the address of the 4 bytes after 0xA1, is written in the relocations table.
If the module is loaded at a different base address, the OS loader enumerates all addresses in the table, finds each 32-bit word the address points to, subtracts the original base address from it (we get the RVA here), and adds the new base address to it.
If a module is loaded at its original base address, nothing happens.

All global variables can be treated like that.
Relocs may have various types, however, in Windows for x86 processors, the type is usually IMAGE_REL_BASED_HIGHLOW.

By the way, relocations are darkened in Hiew, for example: fig.1.22. (You have to circumvent these bytes during patching.)
OllyDbg underlines the places in memory to which relocations are to be applied, for example: fig.1.53.

Exports and imports

As we all know, any executable program must use the OS’s services and other DLL-libraries somehow.
It can be said that functions from one module (usually DLL) must be connected somehow to the points of their calls in other modules (.exe-file or another DLL).
For this, each DLL has an “exports” table, which consists of functions plus their addresses in a module.
And every .exe file or DLL has “imports”, a table of functions it needs for execution including list of DLL filenames.

30 Even in .exe files for MS-DOS

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
After loading the main .exe-file, the OS loader processes imports table: it loads the additional DLL-files, finds function names among the DLL exports and writes their addresses down in the IAT of the main .exe-module.

As we can see, during loading the loader must compare a lot of function names, but string comparison is not a very fast procedure, so there is a support for “ordinals” or “hints”, which are function numbers stored in the table, instead of their names.

That is how they can be located faster when loading a DLL. Ordinals are always present in the “export” table.

For example, a program using the MFC\textsuperscript{31} library usually loads mfc*.dll by ordinals, and in such programs there are no MFC function names in INT.

When loading such programs in IDA, it will ask for a path to the mfc*.dll files in order to determine the function names.

If you don’t tell IDA the path to these DLLs, there will be \textit{mfc80_123} instead of function names.

\textbf{Imports section}

Often a separate section is allocated for the imports table and everything related to it (with name like .idata), however, this is not a strict rule.

Imports are also a confusing subject because of the terminological mess. Let’s try to collect all information in one place.

\textsuperscript{31}Microsoft Foundation Classes

(For statistics collecting purposes) if you’ve read this far, please click \url{here}. Thanks!
The main structure is the array `IMAGE_IMPORT_DESCRIPTOR`. Each element for each DLL being imported. Each element holds the RVA address of the text string (DLL name) (Name).

`OriginalFirstThunk` is the RVA address of the INT table. This is an array of RVA addresses, each of which points to a text string with a function name. Each string is prefixed by a 16-bit integer (“hint”)—“ordinal” of function.

While loading, if it is possible to find a function by ordinal, then the strings comparison will not occur. The array is terminated by zero.

There is also a pointer to the IAT table named `FirstThunk`, it is just the RVA address of the place where the loader writes the addresses of the resolved functions.

The points where the loader writes addresses are marked by IDA like this: `_imp_CreateFileA`, etc.

There are at least two ways to use the addresses written by the loader.

- The code will have instructions like `call _imp_CreateFileA`, and since the field with the address of
the imported function is a global variable in some sense, the address of the call instruction (plus 1 or 2) is to be added to the relocs table, for the case when the module is loaded at a different base address.

But, obviously, this may enlarge relocs table significantly.

Because there are might be a lot of calls to imported functions in the module.

Furthermore, large relocs table slows down the process of loading modules.

• For each imported function, there is only one jump allocated, using the JMP instruction plus a reloc to it. Such points are also called “thunks”.

All calls to the imported functions are just CALL instructions to the corresponding “thunk”. In this case, additional relocs are not necessary because these CALL-s have relative addresses and do not need to be corrected.

These two methods can be combined.

Possible, the linker creates individual “thunk”s if there are too many calls to the function, but not done by default.

By the way, the array of function addresses to which FirstThunk is pointing is not necessary to be located in the IAT section. For example, the author of these lines once wrote the PE_add_import utility for adding imports to an existing .exe-file.

Some time earlier, in the previous versions of the utility, at the place of the function you want to substitute with a call to another DLL, my utility wrote the following code:

```
MOV EAX, [yourdll.dll!function]
JMP EAX
```

FirstThunk points to the first instruction. In other words, when loading yourdll.dll, the loader writes the address of the function function right in the code.

It also worth noting that a code section is usually write-protected, so my utility adds the IMAGE_SCN_MEM_WRITE flag for code section. Otherwise, the program to crash while loading with error code 5 (access denied).

One might ask: what if I supply a program with a set of DLL files which is not supposed to change (including addresses of all DLL functions), is it possible to speed up the loading process?

Yes, it is possible to write the addresses of the functions to be imported into the FirstThunk arrays in advance. The Timestamp field is present in the IMAGE_IMPORT_DESCRIPTOR structure.

If a value is present there, then the loader compares this value with the date-time of the DLL file.

If the values are equal, then the loader does not do anything, and the loading of the process can be faster. This is called “old-style binding” 33.

The BIND.EXE utility in Windows SDK is for this. For speeding up the loading of your program, Matt Pietrek in Matt Pietrek, An In-Depth Look into the Win32 Portable Executable File Format, (2002)] 34, suggests to do the binding shortly after your program installation on the computer of the end user.

PE-files packers/encryptors may also compress/encrypt imports table.

In this case, the Windows loader, of course, will not load all necessary DLLs.

Therefore, the packer/encryptor does this on its own, with the help of LoadLibrary() and the GetProcAddress() functions.

That is why these two functions are often present in IAT in packed files.

In the standard DLLs from the Windows installation, IAT often is located right at the beginning of the PE file. Supposedly, it is made so for optimization.

While loading, the .exe file is not loaded into memory as a whole (recall huge install programs which are started suspiciously fast), it is “mapped”, and loaded into memory in parts as they are accessed.

Probably, Microsoft developers decided it will be faster.

32 yurichev.com
33 MSDN. There is also the “new-style binding”.

Resources

Resources in a PE file are just a set of icons, pictures, text strings, dialog descriptions. Perhaps they were separated from the main code, so all these things could be multilingual, and it would be simpler to pick text or picture for the language that is currently set in the OS.

As a side effect, they can be edited easily and saved back to the executable file, even if one does not have special knowledge, by using the ResHack editor, for example (6.5.2).

.NET

.NET programs are not compiled into machine code but into a special bytecode. Strictly speaking, there is bytecode instead of the usual x86 code in the .exe file, however, the entry point (OEP) points to this tiny fragment of x86 code:

```
jmp  mscorere.d!!_CorExeMain
```

The .NET loader is located in mscorere.d.dll, which processes the PE file.

It was so in all pre-Windows XP OSes. Starting from XP, the OS loader is able to detect the .NET file and run it without executing that JMP instruction 35.

TLS

This section holds initialized data for the TLS(6.2 on page 741) (if needed). When a new thread start, its TLS data is initialized using the data from this section.

Aside from that, the PE file specification also provides initialization of the TLS section, the so-called TLS callbacks.

If they are present, they are to be called before the control is passed to the main entry point (OEP).

This is used widely in the PE file packers/encryptors.

Tools

• objdump (present in cygwin) for dumping all PE-file structures.
• Hiew(7.1 on page 789) as editor.
• pefile—Python-library for PE-file processing 36.
• ResHack AKA Resource Hacker—resources editor37.
• PE_add_import38—simple tool for adding symbol(s) to PE executable import table.
• PE_patcher39—simple tool for patching PE executables.
• PE_search_str.refs40—simple tool for searching for a function in PE executables which use some text string.

6.5.3 Windows SEH

Let’s forget about MSVC

In Windows, the SEH is intended for exceptions handling, nevertheless, it is language-agnostic, not related to C++ or OOP in any way.

Here we are going to take a look at SEH in its isolated (from C++ and MSVC extensions) form.

Each running process has a chain of SEH handlers, each TIB has the address of the most recently defined handler.

When an exception occurs (division by zero, incorrect address access, user exception triggered by calling the RaiseException() function), the OS finds the last handler in the TIB and calls it, passing exception kind and all information about the CPU state (register values, etc.) at the moment of the exception.

The exception handler considering the exception, does it see something familiar? If so, it handles the exception.

If not, it signals to the OS that it cannot handle it and the OS calls the next handler in the chain, until a handler which is able to handle the exception is be found.

At the very end of the chain there a standard handler that shows the well-known dialog box, informing the user about a process crash, some technical information about the CPU state at the time of the crash, and offering to collect all information and send it to developers in Microsoft.

![crash.exe](image)

**crash.exe**

**crash.exe has encountered a problem and needs to close. We are sorry for the inconvenience.**

If you were in the middle of something, the information you were working on might be lost.

**Please tell Microsoft about this problem.**

We have created an error report that you can send to us. We will treat this report as confidential and anonymous.

[Send Error Report] [Don’t Send]

Figure 6.2: Windows XP
Figure 6.3: Windows XP

Figure 6.4: Windows 7
Earlier, this handler was called Dr. Watson \(^{42}\).

By the way, some developers make their own handler that sends information about the program crash to themselves. It is registered with the help of `SetUnhandledExceptionFilter()` and to be called if the OS does not have any other way to handle the exception. An example is Oracle RDBMS—it saves huge dumps reporting all possible information about the CPU and memory state.

Let's write our own primitive exception handler. This example is based on the example from [Matt Pietrek, *A Crash Course on the Depths of Win32™ Structured Exception Handling*, (1997)](http://go.yurichev.com/17293)\(^{43}\). It must be compiled with the SAFESEH option: `cl seh1.cpp /link /safeseh:no`. More about SAFESEH here: [MSDN](http://go.yurichev.com/17293).

```c
#include <windows.h>
#include <stdio.h>

DWORD new_value=1234;

EXCEPTION_DISPOSITION cdecl except_handler(
    struct _EXCEPTION_RECORD *ExceptionRecord,
    void *EstablisherFrame,
    struct _CONTEXT *ContextRecord,
    void *DispatcherContext )
{
    unsigned i;

    printf ("%s\n", __FUNCTION__);
    printf ("ExceptionRecord->ExceptionCode=0x%p\n", ExceptionRecord->ExceptionCode);
    printf ("ExceptionRecord->ExceptionFlags=0x%p\n", ExceptionRecord->ExceptionFlags);
    printf ("ExceptionRecord->ExceptionAddress=0x%p\n", ExceptionRecord->ExceptionAddress);

    if (ExceptionRecord->ExceptionCode==0xE1223344)
    {
        printf ("That's for us\n");
        // yes, we "handled" the exception
        return ExceptionContinueExecution;
    }
    else if (ExceptionRecord->ExceptionCode==EXCEPTION_ACCESS_VIOLATION)
    {
        printf ("ContextRecord->Eax=0x%08X\n", ContextRecord->Eax);
        // will it be possible to 'fix' it?
        printf ("Trying to fix wrong pointer address\n");
        ContextRecord->Eax=(DWORD)&new_value;
        // yes, we "handled" the exception
        return ExceptionContinueExecution;
    }
    else
    {
        printf ("We do not handle this\n");
        // someone else's problem
        return ExceptionContinueSearch;
    }
}
```

\(^{42}\)wikipedia
\(^{43}\)Also available as [http://go.yurichev.com/17293](http://go.yurichev.com/17293)

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
int main()
{
    DWORD handler = (DWORD)except_handler; // take a pointer to our handler

    // install exception handler
    __asm
    {
        push handler      // make EXCEPTION_REGISTRATION record:
        push FS:[0]       // address of handler function
        mov FS:[0],ESP   // address of previous handler
        // add new EXCEPTION_REGISTRATION
    }
    RaiseException (0xE1223344, 0, 0, NULL);

    // now do something very bad
    int* ptr=NULL;
    int val=0;
    val=*ptr;
    printf ("val=%d\n", val);

    // deinstall exception handler
    __asm
    {
        mov eax,[ESP]   // remove our EXCEPTION_REGISTRATION record
        add esp, 8     // clean our EXCEPTION_REGISTRATION off stack
    }
    return 0;
}

The FS: segment register is pointing to the TIB in win32.

The very first element in the TIB is a pointer to the last handler in the chain. We save it in the stack and store the address of our handler there. The structure is named _EXCEPTION_REGISTRATION, it is a simple singly-linked list and its elements are stored right in the stack.

Listing 6.22: MSVC/VC/crt/src/exsup.inc

_EXCEPTION_REGISTRATION struc
    prev dd ?,
    handler dd ?,
_EXCEPTION_REGISTRATION ends

So each “handler” field points to a handler and an each “prev” field points to the previous record in the chain of exception handlers. The last record has 0xFFFFFFFF (-1) in the “prev” field.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
After our handler is installed, we call RaiseException(). This is an user exception. The handler checks the code. If the code is 0xE1223344, it returning ExceptionContinueExecution, which means that handler corrected the CPU state (it is usually a correction of the EIP/ESP registers) and the OS can resume the execution of the thread. If you alter slightly the code so the handler returns ExceptionContinueSearch, then the OS will call the other handlers, and it’s unlikely that one who can handle it will be found, since no one will have any information about it (rather about its code). You will see the standard Windows dialog about a process crash.

What is the difference between a system exceptions and a user one? Here are the system ones:

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXCEPTION_ACCESS_VIOLATION</td>

<td>0x80000001</td>
</tr>
<tr>
<td>EXCEPTION_INVALID_HANDLE</td>
<td>0xC0000008</td>
</tr>
<tr>
<td>EXCEPTION_POSSIBLE_DEADLOCK</td>
<td>0xC0000194</td>
</tr>
<tr>
<td>CONTROL_C_EXIT</td>
<td>0xC000013A</td>
</tr>
</tbody>
</table>

That is how the code is defined:

<table>
<thead>
<tr>
<th>S</th>
<th>U</th>
<th>0</th>
<th>Facility code</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>0</td>
<td>Error code</td>
</tr>
</tbody>
</table>

S is a basic status code: 11—error; 10—warning; 01—informational; 00—success. U—whether the code is user code.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
That is why we chose 0xE123344—E16 (11102) 0xE (1110b) means that it is 1) user exception; 2) error.

But to be honest, this example works fine without these high bits.

Then we try to read a value from memory at address 0.

Of course, there is nothing at this address in win32, so an exception is raised.

The very first handler is to be called—yours, and it will know about it first, by checking the code if it’s equal to the EXCEPTION_ACCESS_VIOLATION constant.

The code that’s reading from memory at address 0 is looks like this:

```
Listing 6.23: MSVC 2010
...
xor eax, eax
mov eax, DWORD PTR [eax] ; exception will occur here
push eax
push OFFSET msg
call _printf
add esp, 8
...
```

Will it be possible to fix this error “on the fly” and to continue with program execution?

Yes, our exception handler can fix the EAX value and let the OS execute this instruction once again. So that is what we do. printf() prints 1234, because after the execution of our handler EAX is not 0, but contains the address of the global variable new_value. The execution will resume.

That is what is going on: the memory manager in the CPU signals about an error, the CPU suspends the thread, finds the exception handler in the Windows kernel, which, in turn, starts to call all handlers in the SEH chain, one by one.

We use MSVC 2010 here, but of course, there is no any guarantee that EAX will be used for this pointer.

This address replacement trick is showy, and we considering it here as an illustration of SEH’s internals. Nevertheless, it’s hard to recall any case where it is used for “on-the-fly” error fixing.

Why SEH-related records are stored right in the stack instead of some other place?

Supposedly because the OS is not needing to care about freeing this information, these records are simply disposed when the function finishes its execution. This is somewhat like alloca(): (1.9.2 on page 34).

**Now let’s get back to MSVC**

Supposedly, Microsoft programmers needed exceptions in C, but not in C++ (for use in Windows NT kernel, which is written in C), so they added a non-standard C extension to MSVC. It is not related to C++ PL exceptions.

```
__try
{
    ...
}
__except(filter code)
{
    handler code
}
```

“Finally” block may be instead of handler code:

```
__try
{
    ...
}
finally
{
    ...
}
```

---

45 MSDN

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The filter code is an expression, telling whether this handler code corresponds to the exception raised. If your code is too big and cannot fit into one expression, a separate filter function can be defined.

There are a lot of such constructs in the Windows kernel. Here are a couple of examples from there (WRK):

**Listing 6.24: WRK-v1.2/base/ntos/ob/obwait.c**

```c
try {
    KeReleaseMutant((PKMUTANT)SignalObject,
            MUTANT_INCREMENT,
            FALSE,
            TRUE);
} except((GetExceptionCode () == STATUS_ABANDONED ||
    GetExceptionCode () == STATUS_MUTANT_NOT_OWNED)?
    EXCEPTION_EXECUTE_HANDLER :
    EXCEPTION_CONTINUE_SEARCH) {
    Status = GetExceptionCode();
    goto WaitExit;
}
```

**Listing 6.25: WRK-v1.2/base/ntos/cache/cachesub.c**

```c
try {
    RtlCopyBytes((PVOID)((PCHAR)CacheBuffer + PageOffset),
            UserBuffer,
            MorePages ?
            (PAGE_SIZE - PageOffset) :
            (ReceivedLength - PageOffset));
} except(CcCopyReadExceptionFilter( GetExceptionInformation(),
                                        &Status )) {
```

Here is also a filter code example:

**Listing 6.26: WRK-v1.2/base/ntos/cache/copysup.c**

```c
LONG CcCopyReadExceptionFilter( 
    IN PEXCEPTION_POINTERS ExceptionPointer, 
    IN PNTSTATUS ExceptionCode 
) 

/**++
Routine Description:
   This routine serves as an exception filter and has the special job of 
   extracting the "real" I/O error when Mm raises STATUS_IN_PAGE_ERROR 
   beneath us.
Arguments:
    ExceptionPointer - A pointer to the exception record that contains 
                       the real Io Status.
    ExceptionCode - A pointer to an NTSTATUS that is to receive the real 
                    status.
Return Value:
    EXCEPTION_EXECUTE_HANDLER 
--*/
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
*ExceptionCode = ExceptionPointer->ExceptionRecord->ExceptionCode;

if ((*ExceptionCode == STATUS_IN_PAGE_ERROR) &&
    (ExceptionPointer->ExceptionRecord->NumberParameters >= 3)) {
    *ExceptionCode = (NTSTATUS) ExceptionPointer->ExceptionRecord->ExceptionInformation[2];
}

ASSERT(!NT_SUCCESS(*ExceptionCode));
return EXCEPTION_EXECUTE_HANDLER;

Internally, SEH is an extension of the OS-supported exceptions. But the handler function is _except_handler3 (for SEH3) or _except_handler4 (for SEH4).
The code of this handler is MSVC-related, it is located in its libraries, or in msvcr*.dll. It is very important to know that SEH is a MSVC thing.
Other win32-compilers may offer something completely different.

**SEH3**

SEH3 has _except_handler3 as a handler function, and extends the _EXCEPTION_REGISTRATION table, adding a pointer to the scope table and previous try level variable. SEH4 extends the scope table by 4 values for buffer overflow protection.

The scope table is a table that consists of pointers to the filter and handler code blocks, for each nested level of try/except.
Again, it is very important to understand that the OS takes care only of the prev/handle fields, and nothing more. It is the job of the _except_handler3 function to read the other fields and scope table, and decide which handler to execute and when.

The source code of the _except_handler3 function is closed.

However, Sanos OS, which has a win32 compatibility layer, has the same functions reimplemented, which are somewhat equivalent to those in Windows. Another reimplementation is present in Wine and ReactOS.

If the filter pointer is NULL, the handler pointer is the pointer to the finally code block.

During execution, the previous try level value in the stack changes, so _except_handler3 can get information about the current level of nestedness, in order to know which scope table entry to use.

**SEH3: one try/except block example**

```c
#include <stdio.h>
#include <windows.h>
#include <excpt.h>

int main()
{
    int* p = NULL;

    // Example code
    // ...

    return 0;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```c
__try
{
    printf("hello #1!\n");
    *p = 13; // causes an access violation exception;
    printf("hello #2!\n");
}
__except(GetExceptionCode() == EXCEPTION_ACCESS_VIOLATION ?
    EXCEPTION_EXECUTE_HANDLER : EXCEPTION_CONTINUE_SEARCH)
{
    printf("access violation, can't recover\n");
}
```

Listing 6.27: MSVC 2003

Here we see how the SEH frame is constructed in the stack. The scope table is located in the CONST segment—indeed, these fields are not to be changed. An interesting thing is how the previous try level variable has changed. The initial value is 0xFFFFFFFF (−1). The moment when the body of the try statement is opened is marked with an instruction that writes 0 to the variable. The moment when the body of the try statement is closed, −1 is written back to it. We also see the addresses of filter and handler code. Thus we can easily see the structure of the try/except constructs in the function.

Since the SEH setup code in the function prologue may be shared between many functions, sometimes the compiler inserts a call to the SEH_prolog() function in the prologue, which does just that.

The SEH cleanup code is in the SEH_epilog() function.

Let's try to run this example in tracer:

tracer.exe -l:2.exe --dump-seh

Listing 6.28: tracer.exe output

We see that the SEH chain consists of 4 handlers.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The first two are located in our example. Two? But we made only one? Yes, another one has been set up in the CRT function _mainCRTStartup(), and as it seems that it handles at least FPU exceptions. Its source code can be found in the MSVC installation: crt/src/winxfltr.c.

The third is the SEH4 one in ntdll.dll, and the fourth handler is not MSVC-related and is located in nt.dll.dll, and has a self-describing function name.

As you can see, there are 3 types of handlers in one chain:

one is not related to MSVC at all (the last one) and two MSVC-related: SEH3 and SEH4.

**SEH3: two try/except blocks example**

```c
#include <stdio.h>
#include <windows.h>
#include <excpt.h>

int filter_user_exceptions (unsigned int code, struct _EXCEPTION_POINTERS *ep)
{
    printf("in filter. code=0x%08X\n", code);
    if (code == 0x112233)
    {
        printf("yes, that is our exception\n");
        return EXCEPTION_EXECUTE_HANDLER;
    }
    else
    {
        printf("not our exception\n");
        return EXCEPTION_CONTINUE_SEARCH;
    }
}

int main()
{
    int* p = NULL;
    __try
    {
        __try
        {
            printf("hello!\n");
            RaiseException (0x112233, 0, 0, NULL);
            printf("0x112233 raised. now let's crash\n");
            *p = 13; // causes an access violation exception;
        }
        __except(GetExceptionCode() == EXCEPTION_ACCESS_VIOLATION ?
            EXCEPTION_EXECUTE_HANDLER : EXCEPTION_CONTINUE_SEARCH)
        {
            printf("access violation, can't recover\n");
        }
        __except(filter_user_exceptions(GetExceptionCode(), GetExceptionInformation))
        {
            // the filter_user_exceptions() function answering to the question
            // "is this exception belongs to this block?"
            // if yes, do the follow:
            printf("user exception caught\n");
        }
    }
    __try
    {
        printf("yes, that is our exception\n");
        return EXCEPTION_EXECUTE_HANDLER;
    }
    __except(filter_user_exceptions(GetExceptionCode(), GetExceptionInformation()))
    {
        // the filter_user_exceptions() function answering to the question
        // "is this exception belongs to this block?"
        // if yes, do the follow:
        printf("user exception caught\n");
    }
}
```

Now there are two try blocks. So the scope table now has two entries, one for each block. Previous try level changes as execution flow enters or exits the try block.

Listing 6.29: MSVC 2003

```
$SG74606  DB 'in filter. code=0x%08X', 0AH, 00H
$SG74608  DB 'yes, that is our exception', 0AH, 00H
$SG74610  DB 'not our exception', 0AH, 00H
$SG74617  DB 'hello!', 0AH, 00H
$SG74619  DB '0x112233 raised. now let''s crash', 0AH, 00H

If we set a breakpoint on the printf() function, which is called from the handler, we can also see how yet another SEH handler is added.
Perhaps it's another machinery inside the SEH handling process. Here we also see our scope table consisting of 2 entries.

tracer.exe -l:3.exe bpx=3.exe!printf --dump-seh

Listing 6.30: tracer.exe output

SEH4

During a buffer overflow (1.26.2 on page 275) attack, the address of the scope table can be rewritten, so starting from MSVC 2005, SEH3 was upgraded to SEH4 in order to have buffer overflow protection. The pointer to the scope table is now xor'd with a security cookie. The scope table was extended to have a header consisting of two pointers to security cookies.

Each element has an offset inside the stack of another value: the address of the stack frame (EBP) xor'd with the security_cookie, placed in the stack.

This value will be read during exception handling and checked for correctness. The security cookie in the stack is random each time, so hopefully a remote attacker can’t predict it.

The initial previous try level is −2 in SEH4 instead of −1.
Here are both examples compiled in MSVC 2012 with SEH4:

Listing 6.31: MSVC 2012: one try block example

Here is the meaning of the cookies: Cookie Offset is the difference between the address of the saved EBP value in the stack and the $EBP⊕security_cookie$ value in the stack. Cookie XOR Offset is an additional difference between the $EBP⊕security_cookie$ value and what is stored in the stack.

If this equation is not true, the process is to halt due to stack corruption:

$$security_cookie@(CookieXOROffset+address\_of\_saved\_EBP) == stack[address\_of\_saved\_EBP+CookieOffset]$$

If Cookie Offset is \(-2\), this implies that it is not present.

Cookies checking is also implemented in my tracer, see GitHub for details.

It is still possible to fall back to SEH3 in the compilers after (and including) MSVC 2005 by setting the /GS- option, however, the CRT code use SEH4 anyway.

Windows x64

As you might think, it is not very fast to set up the SEH frame at each function prologue. Another performance problem is changing the previous try level value many times during the function’s execution.

So things are changed completely in x64: now all pointers to try blocks, filter and handler functions are stored in another PE segment .pdata, and from there the OS’s exception handler takes all the information.

Here are the two examples from the previous section compiled for x64:

```
Listing 6.33: MSVC 2012

filter_user_exceptions ENDP  

_TEXT ENDS  

Read [Igor Skochinsky, Compiler Internals: Exceptions and RTTI, (2012)](http://go.yurichev.com/17294) for more detailed information about this.

Aside from exception information, .pdata is a section that contains the addresses of almost all function starts and ends, hence it may be useful for a tools targeted at automated analysis.

---

49Also available as http://go.yurichev.com/17294
Critical sections in any **OS** are very important in multithreaded environment, mostly for giving a guarantee that only one thread can access some data in a single moment of time, while blocking other threads and interrupts.

That is how a CRITICAL_SECTION structure is declared in **Windows NT** line OS:

```c
typedef struct _RTL_CRITICAL_SECTION {
    PRTL_CRITICAL_SECTION_DEBUG DebugInfo;
    //
    // The following three fields control entering and exiting the critical
    // section for the resource
    //
    LONG LockCount;
    LONG RecursionCount;
    HANDLE OwningThread;       // from the thread's ClientId->UniqueThread
    HANDLE LockSemaphore;
    ULONG_PTR SpinCount;       // force size on 64-bit systems when packed
} RTL_CRITICAL_SECTION, *PRTL_CRITICAL_SECTION;
```

That's is how EnterCriticalSection() function works:

```c
RtlEnterCriticalSection@4

var_C = dword ptr -0Ch
var_8 = dword ptr -8
var_4 = dword ptr -4
arg_0 = dword ptr 8

mov   edi, edi
push  ebp
mov   ebp, esp
sub   esp, 0Ch
push  esi
push  edi
mov   edi, [ebp+arg_0]
lea   esi, [edi+4]; LockCount
mov   eax, esi
lock btr dword ptr [eax], 0
jnb   wait ; jump if CF=0

loc_7DE922DD:

mov   eax, large fs:18h
mov   ecx, [eax+24h]
mov   [edi+0Ch], ecx
mov   dword ptr [edi+8], 1
pop   edi
xor   eax, eax
pop   esi
mov   esp, ebp
pop   ebp
retn  4
```

(For statistics collecting purposes) if you’ve read this far, please click **here**. Thanks!

---

[^51]: Also available as [http://go.yurichev.com/17294](http://go.yurichev.com/17294)
The most important instruction in this code fragment is BTR (prefixed with LOCK):
the zeroth bit is stored in the CF flag and cleared in memory. This is an atomic operation,
blocking all other CPUs’ access to this piece of memory (see the LOCK prefix before the BTR instruction).
If the bit at LockCount is 1,
fine, reset it and return from the function: we are in a critical section.
If not—the critical section is already occupied by other thread, so wait.
The wait is performed there using WaitForSingleObject().

And here is how the LeaveCriticalSection() function works:

    Listing 6.37: Windows 2008/ntdll.dll/x86 (begin)

```
_RtlLeaveCriticalSection@4 proc near
arg_0 = dword ptr 8

    mov   edi, edi
    push  ebp
    mov   ebp, esp
    push  esi
    mov   esi, [ebp+arg_0]
    add   dword ptr [esi+8], 0FFFFFFFFh ; RecursionCount
    jnz   short loc_7DE922B2
    push  ebx
    push  edi
    lea   edi, [esi+4] ; LockCount
    mov   dword ptr [esi+0Ch], 0
    mov   ebx, 1
    mov   eax, edi
    lock xadd [eax], ebx
    inc   ebx
    cmp   ebx, 0FFFFFFFFh
    jnz   loc_7DEA8EB7

loc_7DE922B0:
    pop   edi
    pop   ebx

loc_7DEA8EB7:
    xor   eax, eax
    pop   esi
    pop   ebp
    retn  4
```

XADD is “exchange and add”.
In this case, it adds 1 to LockCount, meanwhile saves initial value of LockCount in the EBX register.
However, value in EBX is to incremented with a help of subsequent INC EBX, and it also will be equal to the updated value of LockCount.

This operation is atomic since it is prefixed by LOCK as well, meaning that all other CPUs or CPU cores in system are blocked from accessing this point in memory.

The LOCK prefix is very important:
without it two threads, each of which works on separate CPU or CPU core can try to enter a critical section and to modify the value in memory, which will result in non-deterministic behavior.
Chapter 7

Tools

Now that Dennis Yurichev has made this book free (libre), it is a contribution to the world of free knowledge and free education. However, for our freedom’s sake, we need free (libre) reverse engineering tools to replace the proprietary tools described in this book.

Richard M. Stallman

7.1 Binary analysis

Tools you use when you don’t run any process.

• (Free, open-source) ent\(^1\): entropy analyzing tool. Read more about entropy: 9.2 on page 920.

• Hiew\(^2\): for small modifications of code in binary files. Has assembler/disassembler.

• (Free, open-source) GHex\(^3\): simple hexadecimal editor for Linux.

• (Free, open-source) xxd and od: standard UNIX utilities for dumping.

• (Free, open-source) strings: *NIX tool for searching for ASCII strings in binary files, including executable ones. Sysinternals has alternative\(^4\) supporting wide char strings (UTF-16, widely used in Windows).

• (Free, open-source) Binwalk\(^5\): analyzing firmware images.

• (Free, open-source) binary grep: a small utility for searching any byte sequence in a big pile of files, including non-executable ones: GitHub. There is also rafind2 in rada.re for the same purpose.

7.1.1 Disassemblers

• IDA. An older freeware version is available for download\(^6\). Hot-keys cheatsheet: 6.1 on page 1017

• Binary Ninja\(^7\)

• (Free, open-source) zynamics BinNavi\(^8\)

• (Free, open-source) objdump: simple command-line utility for dumping and disassembling.

• (Free, open-source) readelf\(^9\): dump information about ELF file.

---

\(^1\)http://www.fourmilab.ch/random/

\(^2\)hiew.ru

\(^3\)https://wiki.gnome.org/Apps/Ghex

\(^4\)https://technet.microsoft.com/en-us/sysinternals/strings

\(^5\)http://binwalk.org/

\(^6\)hex-rays.com/products/ida/support/download_freeware.shtml

\(^7\)http://binary.ninja/

\(^8\)https://www.zynamics.com/binnavi.html

\(^9\)https://sourceware.org/binutils/docs/binutils/readelf.html
7.1.2 Decompilers

There is only one known, publicly available, high-quality decompiler to C code: Hex-Rays: hex-rays.com/products/decompiler/
Read more about it: 11.8 on page 979.

7.1.3 Patch comparison/diffing

You may want to use it when you compare original version of some executable and patched one, in order to find what has been patched and why.

- (Free) zynamics BinDiff\(^\text{10}\)
- (Free, open-source) Diaphora\(^\text{11}\)

7.2 Live analysis

Tools you use on a live system or during running of a process.

7.2.1 Debuggers

- (Free) OllyDbg. Very popular user-mode win32 debugger\(^\text{12}\). Hot-keys cheatsheet: .6.2 on page 1017
- (Free, open-source) GDB. Not quite popular debugger among reverse engineers, because it’s intended mostly for programmers. Some commands: .6.5 on page 1018. There is a visual interface for GDB, “GDB dashboard”\(^\text{13}\).
- (Free, open-source) LLDB\(^\text{14}\).
- WinDbg\(^\text{15}\): kernel debugger for Windows.
- IDA has internal debugger.
- (Free, open-source) Radare AKA rada.re AKA r2\(^\text{16}\). A GUI also exists: ragus\(^\text{17}\).
- (Free, open-source) tracer. The author often uses tracer\(^\text{18}\) instead of a debugger.

The author of these lines stopped using a debugger eventually, since all he needs from it is to spot function arguments while executing, or registers state at some point. Loading a debugger each time is too much, so a small utility called tracer was born. It works from command line, allows intercepting function execution, setting breakpoints at arbitrary places, reading and changing registers state, etc.
N.B.: the tracer isn’t evolving, because it was developed as a demonstration tool for this book, not as everyday tool.

7.2.2 Library calls tracing

ltrace\(^\text{19}\).

7.2.3 System calls tracing

strace / dtruss

It shows which system calls (syscalls( 6.3 on page 746)) are called by a process right now.

For example:

```
# strace df -h

... access("/etc/ld.so.nohwcap", F_OK) = -1 ENOENT (No such file or directory)
open("/lib/i386-linux-gnu/libc.so.6", 0_RDONLY|O_CLOEXEC) = 3
read(3, ":\177ELF\1\1\1\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0\0...", 512) = 512
fstat64(3, {st_mode=S_IFREG|0755, st_size=1770984, ...}) = 0
mmap2(NULL, 1780508, PROT_READ|PROT_EXEC, MAP_PRIVATE|MAP_DENYWRITE, 3, 0) = 0xb75b3000
```

Mac OS X has dtruss for doing the same.

Cygwin also has strace, but as far as it’s known, it works only for .exe-files compiled for the cygwin environment itself.

7.2.4 Network sniffing

Sniffing is intercepting some information you may be interested in.

(Free, open-source) Wireshark20 for network sniffing. It has also capability for USB sniffing21.

Wireshark has a younger (or older) brother tcpdump22, simpler command-line tool.

7.2.5 Sysinternals

(Free) Sysinternals (developed by Mark Russinovich) 23. At least these tools are important and worth studying: Process Explorer, Handle, VMMMap, TCPView, Process Monitor.

7.2.6 Valgrind

(Free, open-source) a powerful tool for detecting memory leaks: http://valgrind.org/. Due to its powerful JIT mechanism, Valgrind is used as a framework for other tools.

7.2.7 Emulators

- (Free, open-source) QEMU24: emulator for various CPUs and architectures.
- (Free, open-source) DosBox25: MS-DOS emulator, mostly used for retrogaming.
- (Free, open-source) SimH26: emulator of ancient computers, mainframes, etc.

---

20https://www.wireshark.org/
21https://wiki.wireshark.org/CaptureSetup/USB
22http://www.tcpdump.org/
24http://qemu.org
25https://www.dosbox.com/
26http://simh.trailing-edge.com/
7.3 Other tools

*Microsoft Visual Studio Express*[^27]: Stripped-down free version of Visual Studio, convenient for simple experiments.

Some useful options: .6.3 on page 1017.

There is a website named “Compiler Explorer”, allowing to compile small code snippets and see output in various GCC versions and architectures (at least x86, ARM, MIPS): [http://godbolt.org/](http://godbolt.org/)—I would have used it myself for the book if I would know about it!

7.3.1 Calculators

Good calculator for reverse engineer's needs should support at least decimal, hexadecimal and binary bases, as well as many important operations like XOR and shifts.

- IDA has built-in calculator (“?”).
- rada.re has *rax2*.
- [https://github.com/DennisYurichev/progcalc](https://github.com/DennisYurichev/progcalc)
- As a last resort, standard calculator in Windows has programmer’s mode.

7.4 Do You Think Something Is Missing Here?

If you know a great tool not listed here, please drop a note: dennis@yurichev.com.

Chapter 8

Case studies
Peter Seibel: How do you tackle reading source code? Even reading something in a programming language you already know is a tricky problem.

Donald Knuth: But it’s really worth it for what it builds in your brain. So how do I do it? There was a machine called the Bunker Ramo 300 and somebody told me that the Fortran compiler for this machine was really amazingly fast, but nobody had any idea why it worked. I got a copy of the source-code listing for it. I didn’t have a manual for the machine, so I wasn’t even sure what the machine language was.

But I took it as an interesting challenge. I could figure out BEGIN and then I would start to decode. The operation codes had some two-letter mnemonics and so I could start to figure out “This probably was a load instruction, this probably was a branch.” And I knew it was a Fortran compiler, so at some point it looked at column seven of a card, and that was where it would tell if it was a comment or not.

After three hours I had figured out a little bit about the machine. Then I found these big, branching tables. So it was a puzzle and I kept just making little charts like I’m working at a security agency trying to decode a secret code. But I knew it worked and I knew it was a Fortran compiler—it wasn’t encrypted in the sense that it was intentionally obscure; it was only in code because I hadn’t gotten the manual for the machine.

Eventually I was able to figure out why this compiler was so fast. Unfortunately it wasn’t because the algorithms were brilliant; it was just because they had used unstructured programming and hand optimized the code to the hilt.

It was just basically the way you solve some kind of an unknown puzzle—make tables and charts and get a little more information here and make a hypothesis. In general when I’m reading a technical paper, it’s the same challenge. I’m trying to get into the author’s mind, trying to figure out what the concept is. The more you learn to read other people’s stuff, the more able you are to invent your own in the future, it seems to me.

( Peter Seibel — Coders at Work: Reflections on the Craft of Programming )

8.1 Task manager practical joke (Windows Vista)

Let’s see if it’s possible to hack Task Manager slightly so it would detect more CPU cores.

Let us first think, how does the Task Manager know the number of cores?

There is the GetSystemInfo() win32 function present in win32 userspace which can tell us this. But it’s not imported in taskmgr.exe.

There is, however, another one in NTAPI, NtQuerySystemInformation(), which is used in taskmgr.exe in several places.

To get the number of cores, one has to call this function with the SystemBasicInformation constant as a first argument (which is zero 1).

The second argument has to point to the buffer which is getting all the information.

So we have to find all calls to the NtQuerySystemInformation(0, ?, ?, ?) function. Let’s open taskmgr.exe in IDA.

What is always good about Microsoft executables is that IDA can download the corresponding PDB file for this executable and show all function names.

It is visible that Task Manager is written in C++ and some of the function names and classes are really speaking for themselves. There are classes CAdapter, CNetPage, CPerfPage, CProcInfo, CProcPage, CSvcPage, CTaskPage, CUserPage.

Apparently, each class corresponds to each tab in Task Manager.

Let’s visit each call and add comment with the value which is passed as the first function argument. We will write “not zero” at some places, because the value there was clearly not zero, but something really different (more about this in the second part of this chapter).

And we are looking for zero passed as argument, after all.

1 MSDN

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Figure 8.1: IDA: cross references to NtQuerySystemInformation()

Yes, the names are really speaking for themselves.

When we closely investigate each place where NtQuerySystemInformation(0, ?, ?, ?) is called, we quickly find what we need in the InitPerfInfo() function:

Listing 8.1: taskmgr.exe (Windows Vista)

```plaintext
.text:10000B483  xor  r9d, r9d
.text:10000B486  lea  rdx, [rsp+0C78h+var_C58] ; buffer
.text:10000B48B  lea  ecx, ecx
.text:10000B48D  lea  ebp, [r9+40h]
.text:10000B49C  mov  r8d, r8d
.text:10000B49F  call  cs:_imp_NtQuerySystemInformation ; 0
.text:10000B4A2  xor  ebx, ebx
.text:10000B4A4  cmp  eax, ebx
.text:10000B4A7  cmp  al, bl
.text:10000B4E9  shr  eax, 0Ah
.text:10000B4EC  lea  r13, !ImageBase
.text:10000B4F7  imul  eax, [rsp+0C78h+var_C4C]
.text:10000B4F8  cmp  [rsp+0C78h+var_C20], bpl
.text:10000B504  mov  cs:_g_MEMMax@3_JA, rax ; __int64 g_MEMMax
.text:10000B507  movzx  eax, [rsp+0C78h+var_C20] ; number of CPUs
.text:10000B509  cmova  eax, ebp
.text:10000B50B  cmp  al, bl
.text:10000B50D  mov  cs:_g_cProcessors@3EA, al ; uchar g_cProcessors
```

g_cProcessors is a global variable, and this name has been assigned by IDA according to the PDB loaded from Microsoft's symbol server.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The byte is taken from var_C20. And var_C58 is passed to NtQuerySystemInformation() as a pointer to the receiving buffer. The difference between 0xC20 and 0xC58 is 0x38 (56).

Let’s take a look at format of the return structure, which we can find in MSDN:

```c
typedef struct _SYSTEM_BASIC_INFORMATION {
    BYTE Reserved1[24];
    PVOID Reserved2[4];
    CCHAR NumberOfProcessors;
} SYSTEM_BASIC_INFORMATION;
```

This is a x64 system, so each PVOID takes 8 bytes.

All reserved fields in the structure take $24 + 4 \times 8 = 56$ bytes.

Oh yes, this implies that var_C20 is the local stack is exactly the NumberOfProcessors field of the SYSTEM_BASIC_INFORMATION structure.

Let’s check our guess. Copy taskmgr.exe from C:\Windows\System32 to some other folder (so the Windows Resource Protection will not try to restore the patched taskmgr.exe).

Let’s open it in Hiew and find the place:

![Figure 8.2: Hiew: find the place to be patched](image1)

Let’s replace the MOVZX instruction with ours. Let’s pretend we’ve got 64 CPU cores.

Add one additional NOP (because our instruction is shorter than the original one):

![Figure 8.3: Hiew: patch it](image2)

And it works! Of course, the data in the graphs is not correct.

At times, Task Manager even shows an overall CPU load of more than 100%.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Figure 8.4: Fooled Windows Task Manager

The biggest number Task Manager does not crash with is 64.

Apparently, Task Manager in Windows Vista was not tested on computers with a large number of cores. So there are probably some static data structure(s) inside it limited to 64 cores.

8.1.1 Using LEA to load values

Sometimes, LEA is used in taskmgr.exe instead of MOV to set the first argument of NtQuerySystemInformation():

Listing 8.2: taskmgr.exe (Windows Vista)

```assembly
xor r9d, r9d
div dword ptr [rsp+4C8h+WndClass.lpfnWndProc]
lea rdx, [rsp+4C8h+VersionInformation]
lea ecx, [r9+2] ; put 2 to ECX
mov r8d, 138h
mov ebx, eax
; ECX=SystemPerformanceInformation
    call cs:__imp_NtQuerySystemInformation ; 2
...

mov r8d, 30h
lea r9, [rsp+298h+var_268]
lea rdx, [rsp+298h+var_258]
lea ecx, [r8-20h] ; put 3 to ECX
; ECX=SystemTimeOfDayInformation
    call cs:__imp_NtQuerySystemInformation ; not zero
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Perhaps MSVC did so because machine code of LEA is shorter than MOV REG, 5 (would be 5 instead of 4). LEA with offset in −128..127 range (offset will occupy 1 byte in opcode) with 32-bit registers is even shorter (for lack of REX prefix)—3 bytes.

Another example of such thing is: 6.1.5 on page 738.
This is a very popular game with several implementations in existence. We can take one of them, called BallTriX, from 1997, available freely at http://go.yurichev.com/17311. Here is how it looks:

![Figure 8.5: This is how the game is usually looks like](image)

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
So let’s see, is it possible to find the random generator and do some trick with it. IDA quickly recognize the standard _rand function in balltrix.exe at 0x00403DA0. IDA also shows that it is called only from one place:

```
.text:00402C9C sub_402C9C proc near ; CODE XREF: sub_402ACA+52
.text:00402C9C ; sub_402ACA+64 ...
.text:00402C9C arg_0 = dword ptr 8
.text:00402C9C push ebp
.text:00402C9D mov ebp, esp
.text:00402C9F push ebx
.text:00402CA0 push esi
.text:00402CA1 push edi
.text:00402CA2 mov eax, dword_40D430
.text:00402CA7 imul eax, dword_40D440
.text:00402CAE add eax, dword_40D5C8
.text:00402CB4 mov ecx, 32000
.text:00402CB9 cdq
.text:00402CBA idiv ecx
.text:00402CBB mov dword_40D440, edx
.text:00402CC2 call _rand
.text:00402CC7 cdq
.text:00402CC8 idiv [ebp+arg_0]
.text:00402CCB mov dword_40D430, edx
.text:00402CD1 mov eax, dword_40D430
.text:00402CD6 jmp $+5
.text:00402D8 pop edi
.text:00402DC5 pop esi
.text:00402DD pop ebx
.text:00402DE leave
.text:00402DF retn
.text:00402DF sub_402C9C endp
```

We’ll call it “random”. Let’s not to dive into this function’s code yet.

This function is referred from 3 places.

Here are the first two:

```
.text:00402B16 mov eax, dword_40C03C ; 10 here
.text:00402B1B push eax
.text:00402B1C call random
.text:00402B21 add esp, 4
.text:00402B24 inc eax
.text:00402B25 mov [ebp+var_C], eax
.text:00402B28 mov eax, dword_40C040 ; 10 here
.text:00402B2D push eax
.text:00402B2E call random
.text:00402B33 add esp, 4
```

Here is the third one:

```
.text:00402B88 mov eax, dword_40C058 ; 5 here
.text:00402B90 push eax
.text:00402B91 call random
.text:00402B96 add esp, 4
.text:00402B99 inc eax
```

So the function has only one argument.

10 is passed in first two cases and 5 in third. We can also notice that the board has a size of 10*10 and there are 5 possible colors. This is it! The standard rand() function returns a number in the 0..0x7FFF range and this is often inconvenient, so many programmers implement their own random functions which returns a random number in a specified range. In our case, the range is 0..n-1 and n is passed as the sole argument of the function. We can quickly check this in any debugger.

So let’s fix the third function call to always return zero. First, we will replace three instructions (PUSH/CALL/ADD) by NOPs. Then we’ll add XOR EAX, EAX instruction, to clear the EAX register.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
So what we did is we replaced a call to the random() function by a code which always returns zero.
Let's run it now:

![Image of Minesweeper game](image)

Figure 8.6: Practical joke works

Oh yes, it works\(^3\).

But why are the arguments to the `random()` functions global variables? That’s just because it’s possible to change the board size in the game’s settings, so these values are not hardcoded. The 10 and 5 values are just defaults.

### 8.3 Minesweeper (Windows XP)

For those who are not very good at playing Minesweeper, we could try to reveal the hidden mines in the debugger.

As we know, Minesweeper places mines randomly, so there has to be some kind of random number generator or a call to the standard `rand()` C-function.

What is really cool about reversing Microsoft products is that there are PDB file with symbols (function names, etc). When we load winmine.exe into IDA, it downloads the PDB file exactly for this executable and shows all names.

So here it is, the only call to `rand()` is this function:

```
.text:01003940 ; __stdcall Rnd(x)
.text:01003940 _Rnd@4          proc near
.text:01003940
.text:01003940 _Rnd@4          arg_0 = dword ptr 4
.text:01003940
.text:01003940 _Rnd@4          call ds:__imp__rand
.text:01003946    cdq
.text:01003947    idiv [esp+arg_0]
.text:01003948    mov eax, edx
.text:0100394d _Rnd@4          ret 4
.text:01003940
```

IDA named it so, and it was the name given to it by Minesweeper’s developers.

The function is very simple:

\(^3\)Author of this book once did this as a joke for his coworkers with the hope that they would stop playing. They didn’t.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
```c
int Rnd(int limit)
{
    return rand() % limit;
}
```

(There is no “limit” name in the PDB file; we manually named this argument like this.)

So it returns a random value from 0 to a specified limit.

Rnd() is called only from one place, a function called StartGame(), and as it seems, this is exactly the code which place the mines:

```c
.data:010036C7 push _xBoxMac
.data:010036CD call _Rnd@4 ; Rnd(x)
.data:010036D2 push _yBoxMac
.data:010036D8 mov esi, eax
.data:010036DA inc esi
.data:010036DB call _Rnd@4 ; Rnd(x)
.data:010036E0 inc eax
.data:010036E1 mov ecx, eax
.data:010036E3 shl ecx, 5 ; ECX=ECX*32
.data:010036E6 test _rgBlk[ecx+esi], 80h
.data:010036EE jnz short loc_10036C7
.data:010036F0 shl eax, 5 ; EAX=EAX*32
.data:010036F3 lea eax, _rgBlk[eax+esi]
.data:010036FA or byte ptr [eax], 80h
.data:010036FD dec cBombStart
.data:01003703 jnz short loc_10036C7
```

Minesweeper allows you to set the board size, so the X (xBoxMac) and Y (yBoxMac) of the board are global variables. They are passed to Rnd() and random coordinates are generated. A mine is placed by the OR instruction at 0x010036FA. And if it has been placed before (it's possible if the pair of Rnd() generates a coordinates pair which has been already generated), then TEST and JNZ at 0x010036E6 jumps to the generation routine again.

cBombStart is the global variable containing total number of mines. So this is loop.

The width of the array is 32 (we can conclude this by looking at the SHR instruction, which multiplies one of the coordinates by 32).

The size of the rgBlk global array can be easily determined by the difference between the rgBlk label in the data segment and the next known one. It is 0x360 (864):

```
.data:01005340 _rgBlk db 360h dup(?); DATA XREF: MainWndProc(x,x,x,x)+574
.data:01005340 ; DisplayBlk(x,x)+23
.data:010056A0 _Preferences dd ?; DATA XREF: FixMenus()+2
```

864/32 = 27.

So the array size is 27 * 32? It is close to what we know: when we try to set board size to 100 * 100 in Minesweeper settings, it fallbacks to a board of size 24 * 30. So this is the maximal board size here. And the array has a fixed size for any board size.

So let’s see all this in OllyDbg. We will run Minesweeper, attaching OllyDbg to it and now we can see the memory dump at the address of the rgBlk array (0x01005340) 4.

So we got this memory dump of the array:

```
Address       Hex dump
01005340 10 10 10 10|10 10 10 10|10 10 10 0F|0F 0F 0F 0F|
01005350 0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
01005360 10 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
01005370 0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
01005380 10 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
01005390 0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
010053A0 10 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
010053B0 0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
010053C0 10 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
```

4All addresses here are for Minesweeper for Windows XP SP3 English. They may differ for other service packs.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
OllyDbg, like any other hexadecimal editor, shows 16 bytes per line. So each 32-byte array row occupies exactly 2 lines here.

This is beginner level (9*9 board).

There is some square structure can be seen visually (0x10 bytes).

We will click “Run” in OllyDbg to unfreeze the Minesweeper process, then we’ll clicked randomly at the Minesweeper window and trapped into mine, but now all mines are visible:

![Minesweeper Window](image)

Figure 8.7: Mines

By comparing the mine places and the dump, we can conclude that 0x10 stands for border, 0x0F—empty block, 0x08F—mine. Perhaps, 0x10 is just a sentinel value.

Now we’ll add comments and also enclose all 0x8F bytes into square brackets:

```plaintext
border:
01005340  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
01005350  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
01005360  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
01005370  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
01005380  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
01005390  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
010053A0  10 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
010053B0  10 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
010053C0  10 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now we’ll remove all border bytes (0x10) and what’s beyond those:

```plaintext
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F[8F]0F 0F[8F]0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
```

Yes, these are mines, now it can be clearly seen and compared with the screenshot.
What is interesting is that we can modify the array right in OllyDbg. We can remove all mines by changing all 0x8F bytes by 0x0F, and here is what we’ll get in Minesweeper:

![Figure 8.8: All mines are removed in debugger](image)

We can also move all of them to the first line:

![Figure 8.9: Mines set in debugger](image)

Well, the debugger is not very convenient for eavesdropping (which is our goal anyway), so we’ll write a small utility to dump the contents of the board:

```c
#include <windows.h>
#include <cassert>
#include <stdio.h>

int main (int argc, char * argv[]) {
    int i, j;
    HANDLE h;
    DWORD PID, address, rd;
    BYTE board[27][32];
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
if (argc!=3)
{
    printf ("Usage: %s <PID> <address>\n", argv[0]);
    return 0;
};

assert (argv[1]!=NULL);
assert (argv[2]!=NULL);

assert (sscanf (argv[1], "%d", &PID)==1);
assert (sscanf (argv[2], "%x", &address)==1);

h=OpenProcess (PROCESS_VM_OPERATION | PROCESS_VM_READ | PROCESS_VM_WRITE, FALSE, PID);
if (h==NULL)
{
    DWORD e=GetLastError();
    printf ("OpenProcess error: %08X\n", e);
    return 0;
};

if (ReadProcessMemory (h, (LPVOID)address, board, sizeof(board), &rd)!=TRUE)
{
    printf ("ReadProcessMemory() failed\n");
    return 0;
};

for (i=1; i<26; i++)
{
    if (board[i][0]==0x10 && board[i][1]==0x10)
        break; // end of board
    for (j=1; j<31; j++)
    {
        if (board[i][j]==0x10)
            break; // board border
        if (board[i][j]==0x8F)
            printf ("*");
        else
            printf (" ");
    }
    printf ("\n");
}

CloseHandle (h);

Just set the PID\(^5\) \(^6\) and the address of the array (0x01005340 for Windows XP SP3 English) and it will dump it \(^7\).

It attaches itself to a win32 process by PID and just reads process memory at the address.

### 8.3.1 Finding grid automatically

This is kind of nuisance to set address each time when we run our utility. Also, various Minesweeper versions may have the array on different address. Knowing the fact that there is always a border (0x10 bytes), we can just find it in memory:

```c
// find frame to determine the address
process_mem=(BYTE*)malloc(process_mem_size);
assert (process_mem!=NULL);

if (ReadProcessMemory (h, (LPVOID)start_addr, process_mem, process_mem_size, &rd)!=TRUE)
```

\(^5\)Program/process ID
\(^6\)PID it can be seen in Task Manager (enable it in "View → Select Columns")
\(^7\)The compiled executable is here: beginners.re

---

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
```c
{    printf ("ReadProcessMemory() failed\n");
    return 0;
};
// for 9*9 grid.
// FIXME: slow!
for (i=0; i<process_mem_size; i++)
{
    if (memcmp(process_mem+i, "\x10\x10\x10\x10\x10\x10\x10\x10\x10\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x0F\x10", 32)
        // found
        address=start_addr+i;
        break;
};
if (address==0)
{
    printf ("Can't determine address of frame (and grid)\n");
    return 0;
} else
{
    printf ("Found frame and grid at 0x%x\n", address);
}
```

### 8.3.2 Exercises

- Why do the **border bytes** (or **sentinel values**) (0x10) exist in the array? What they are for if they are not visible in Minesweeper's interface? How could it work without them?
- As it turns out, there are more values possible (for open blocks, for flagged by user, etc). Try to find the meaning of each one.
- Modify my utility so it can remove all mines or set them in a fixed pattern that you want in the Minesweeper process currently running.

### 8.4 Hacking Windows clock

Sometimes I do some kind of first April prank for my coworkers. Let's find, if we could do something with Windows clock? Can we force to go clock hands backwards?

First of all, when you click on date/time in status bar, a `C:\WINDOWS\SYSTEM32\TIMEDATE.CPL` module gets executed, which is usual executable **PE**-file.

Let's see, how it draw hands? When I open the file (from Windows 7) in Resource Hacker, there are clock faces, but with no hands:

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
OK, what we know? How to draw a clock hand? All they are started at the middle of circle, ending with its border. Hence, we must calculate coordinates of a point on circle’s border. From school-level mathematics we may recall that we have to use sine/cosine functions to draw circle, or at least square root. There are no such things in TIMEDATE.CPL, at least at first glance. But, thanks to Microsoft debugging PDB files, I can find a function named CAnalogClock::DrawHand(), which calls Gdiplus::Graphics::DrawLine() at least twice.

Here is its code:

```
.text:6EB9D8C7 ; private: enum Gdiplus::Status __thiscall CAnalogClock::DrawHand(class Gdiplus::Graphics *, int, struct ClockHand const &, class Gdiplus::Pen *)
.text:6EB9D8C7 ? DrawHand@CAnalogClock@@AAE
\AW4Status@Gdiplus@@PAVGdiplus::Graphics@3@HABUClockHand@@PAVGdiplus::Pen@3@@Z proc near
.text:6EB9D8C7 ; CODE XREF: CAnalogClock::ClockPaint(HDC__ *)+163
.text:6EB9D8C7 ; CAnalogClock::ClockPaint(HDC__ *)+188
.text:6EB9D8C7 var_10 = dword ptr -10h
.text:6EB9D8C7 var_C = dword ptr -0Ch
.text:6EB9D8C7 var_8 = dword ptr -8
.text:6EB9D8C7 var_4 = dword ptr -4
.text:6EB9D8C7 arg_0 = dword ptr 8
.text:6EB9D8C7 arg_4 = dword ptr 0Ch
.text:6EB9D8C7 arg_8 = dword ptr 10h
.text:6EB9D8C7 arg_C = dword ptr 14h
.text:6EB9D8C7 mov edi, edi
.text:6EB9D8C9 push ebp
.text:6EB9D8CA mov ebp, esp
.text:6EB9D8CC sub esp, 10h
.text:6EB9D8CF mov eax, [ebp+arg_4]
.text:6EB9D8D2 push ebx
.text:6EB9D8D3 push esi
.text:6EB9D8D4 push edi
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We can see that DrawLine() arguments are dependent on result of MulDiv() function and a table[] table (name is mine), which has 8-byte elements (look at LEA's second operand).

What is inside of table[]?

It's referenced only from DrawHand() function. It has 120 32-bit words or 60 32-bit pairs... wait, 60? Let's take a closer look at these values. First of all, I'll zap 6 pairs or 12 32-bit words with zeros, and then I'll put patched TIMEDATE.CPL into C:\WINDOWS\SYSTEM32. (You may need to set owner of the *TIMEDATE.CPL* file to your primary user account (instead of TrustedInstaller), and also, boot in safe mode with command prompt so you can copy the file, which is usually locked.)
Now when any hand is located at 0..5 seconds/minutes, it's invisible! However, opposite (shorter) part of second hand is visible and moving. When any hand is outside of this area, hand is visible as usual.

Let's take even closer look at the table in Mathematica. I have copied pasted table from the TIMEDATE.CPL to a tbl file (480 bytes). We will take for granted the fact that these are signed values, because half of elements are below zero (0FFFFE0C1h, etc.). If these values would be unsigned, they would be suspiciously huge.

\[
\text{In[1]:=} \text{tbl} = \text{BinaryReadList["~/.../tbl", "Integer32"]}
\]

\[
\text{Out[1]= \{0, -7999, 836, -7956, 1663, -7825, 2472, -7608, 3253, -7308, 3999, -}
\]

\[
-6928, 4702, -6472, 5353, -5945, 5945, -5353, 6472, -4702, 6928, -}
\]

\[
-4000, 7308, -3253, 7608, -2472, 7285, -1663, 7956, -836, 8000, 0, -}
\]

\[
7956, 836, 7825, 1663, 7608, 2472, 7308, 3253, 6928, 4000, 6472, -}
\]

\[
4702, 5945, 5353, 5353, 5945, 4702, 6472, 3999, 6928, 3253, 7308, -}
\]

\[
2472, 7608, 1663, 7825, 836, 7956, 0, 7999, -836, 7956, -1663, 7825, -}
\]

\[
2472, 7608, -3253, 7308, -4800, 6928, -4702, 6472, -5353, 5945, -}
\]

\[
5945, 5353, -6472, 4702, -6928, 3999, -7308, 3253, -7608, 2472, -}
\]

\[
7825, 1663, -7956, 836, -7999, 0, -7956, -836, -7825, -1663, -7608, -}
\]

\[
2472, -7308, -3253, -6928, -4000, -6472, -4702, -5945, -5353, -5353, -}
\]

\[
5945, -4702, -6472, -3999, -6928, -3253, -7308, -2472, -7608, -1663, -}
\]

\[
7825, -836, -7956}\]

\[
\text{In[2]:=} \text{Length[tbl]}
\]

\[
\text{Out[2]= 120}
\]

Let's treat two consecutive 32-bit values as pair:

\[
\text{In[3]:=} \text{pairs = Partition[tbl, 2]}
\]

\[
\text{Out[3]= \{\{0, -7999\}, \{836, -7956\}, \{1663, -7825\}, \{2472, -7608\}, \}
\]

\[
\{3253, 7308\}, \{3999, -6928\}, \{4702, 6472\}, \{5353, -5945\}, \{5945, -}
\]

\[
5353\}, \{6472, -4702\}, \{6928, -4000\}, \{7308, -3253\}, \{7608, -2472\}, \}
\]

\[
\{7825, 1663\}, \{7956, -836\}, \{8000, 0\}, \{7956, 836\}, \{7825, 1663\}, \}
\]

\[
\{7608, 2472\}, \{7308, 3253\}, \{6928, 4000\}, \{6472, 4702\}, \{5945, 5353\}, \}
\]

\[
\{5353, 5945\}, \{4702, 6472\}, \{3999, 6928\}, \{3253, 7308\}, \{2472, 7608\}, \}
\]

\[
\{1663, 7825\}, \{836, 7956\}, \{0, 7999\}, \{-836, 7956\}, \{-1663, 7825\}, \}
\]

\[
\{-2472, 7608\}, \{-3253, 7308\}, \{-4000, 6928\}, \{-4702, 6472\}, \{-5353, 5945\}, \}
\]

\[
\{-5945, 5353\}, \{-6472, 4702\}, \{-6928, 3999\}, \{-7308, 3253\}, \{-7608, 2472\}, \}
\]

\[
\{-7825, 1663\}, \{-7956, 836\}, \{-7999, 0\}, \{-7956, -836\}, \{-7825, 1663\}, \}
\]

\[
\{-7608, 2472\}, \{-7308, 3253\}, \{-6928, 3999\}, \{-6472, 4702\}, \{-6928, 3999\}, \}
\]

\[
\{-7308, 3253\}, \{-7608, 2472\}, \{-7825, 1663\}, \{-7956, 836\}, \{-7999, 0\}, \}
\]

\[
\{-7956, -836\}, \{-7825, 1663\}, \{-7608, 2472\}, \{-7308, 3253\}, \{-7008, -2472\}, \}
\]

\[
\{-6928, -4702\}, \{-5945, -5353\}, \{-5353, -5945\}, \{-4702, 6472\}, \{-4702, 6472\}, \}
\]

\[
\{-3999, -6928\}, \{-3253, -7308\}, \{-2472, -7608\}, \{-1663, -7825\}, \}
\]

\[
\{-836, -7956\}\}
\]

\[
\text{In[4]:=} \text{Length[pairs]}
\]

\[
\text{Out[4]= 120}
\]
Let’s try to treat each pair as X/Y coordinate and draw all 60 pairs, and also first 15 pairs:

![Mathematica plots of pairs](image)

**Figure 8.12: Mathematica**

Now this is something! Each pair is just coordinate. First 15 pairs are coordinates for \( \frac{1}{4} \) of circle.

Perhaps, Microsoft developers precalculated all coordinates and put them into table. This is widespread, though somewhat old school practice – precalculated table access is faster than calling relatively slow sine/cosine functions\(^8\). Sine/cosine operations are not that expensive anymore...

Now I can understand why when I zapped first 6 pairs, hands were invisible at that area: in fact, hands were drawn, they just had zero length, because hand started at 0:0 coordinate and ended there.

---

\(^8\)Today this is known as *memoization*
The prank (practical joke)

Given all that, how would we force hands to go counterclockwise? In fact, this is simple, we need just to rotate the table, so each hand, instead of drawing at place of zeroth second, would be drawing at place of 59th second.

I made the patcher a long time ago, at the very beginning of 2000s, for Windows 2000. Hard to believe, it still works for Windows 7, perhaps, the table hasn’t been changed since then!

Now I can see all hands goes backwards:

![Figure 8.13: Now it works](image)

Well, there is no animation in this book, but if you look closer, you can see, that hands are in fact shows correct time, but the whole clock face is rotated vertically, like we see it from the inside of clock.

Windows 2000 leaked source code

So I did the patcher and then Windows 2000 source code has been leaked (I can’t force you to trust me, though). Let’s take a look on source code if that function and table.

The file is win2k/private/shell/cpls/utc/clock.c:

```c
// Array containing the sine and cosine values for hand positions.

POINT rCircleTable[] = {
    { 0,  -7999},
    { 836, -7956},
    { 1663, -7825},
    { 2472, -7608},
    { 3253, -7308},
    ...
    { -4702, -6472},
    { -3999, -6928},
    { -3253, -7308},
    { -2472, -7608},
    { -1663, -7825},
    {  -836,  -7956},
};

/////////////////////////////////////////////////////////////////////////

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now it’s clear: coordinates has been precalculated as if clock face has height and width of $2 \cdot 8000$, and then it’s rescaled to current clock face radius using `MulDiv()` function.

POINT structure is a structure of two 32-bit values, first is $x$, second is $y$.

### 8.5 Dongles

The author of these lines, occasionally did software copy-protection dongle replacements, or “dongle emulators” and here are couple examples of how it’s happening.

About one of the cases about Rocket and Z3 that is not present here, you can read here: [http://yurichev.com/tmp/SAT_SMT_DRAFT.pdf](http://yurichev.com/tmp/SAT_SMT_DRAFT.pdf).

#### 8.5.1 Example #1: MacOS Classic and PowerPC

Here is an example of a program for MacOS Classic, for PowerPC. The company who developed the software product has disappeared a long time ago, so the (legal) customer was afraid of physical dongle damage.

While running without a dongle connected, a message box with the text ”Invalid Security Device” appeared.

Luckily, this text string could easily be found in the executable binary file.

Let’s pretend we are not very familiar both with Mac OS Classic and PowerPC, but will try anyway.

IDA opened the executable file smoothly, reported its type as “PEF (Mac OS or Be OS executable)” (indeed, it is a standard Mac OS Classic file format).

By searching for the text string with the error message, we’ve got into this code fragment:

```
seg000:000C87FC 38 60 00 01  li   %r3, 1
seg000:000C8800 48 03 93 41  bl   check1
seg000:000C8804 60 00 00 00  nop
seg000:000C8808 54 60 06 3F  clrlwi. %r0, %r3, 24
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Yes, this is PowerPC code.

The CPU is a very typical 32-bit RISC of 1990s era.

Each instruction occupies 4 bytes (just as in MIPS and ARM) and the names somewhat resemble MIPS instruction names.

`check1()` is a function name we'll give to it later. BL is *Branch Link* instruction, e.g., intended for calling subroutines.

The crucial point is the BNE instruction which jumps if the dongle protection check passes or not if an error occurs: then the address of the text string gets loaded into the r3 register for the subsequent passing into a message box routine.

From the [Steve Zucker, SunSoft and Kari Karhi, IBM, *SYSTEM V APPLICATION BINARY INTERFACE: PowerPC Processor Supplement*, (1995)](http://yurichev.com/mirrors/PowerPC/elfspec_ppc.pdf) we will found out that the r3 register is used for return values (and r4, in case of 64-bit values).

Another yet unknown instruction is CLRLWI. From [PowerPC(tm) Microprocessor Family: The Programming Environments for 32-Bit Microprocessors, (2000)](http://yurichev.com/mirrors/PowerPC/6xx_pem.pdf) we'll learn that this instruction does both clearing and loading. In our case, it clears the 24 high bits from the value in r3 and puts them in r0, so it is analogical to MOVZX in x86 (1.23.1 on page 204), but it also sets the flags, so BNE can check them afterwards.

Let's take a look into the `check1()` function:

```assembly
seg000:00101B40 check1: # CODE XREF: seg000:00063E7Cp
seg000:00101B40 # sub_64070+160p ...
seg000:00101B40 .set arg_8, 8
seg000:00101B40
seg000:00101B40 7C 08 02 A6 mflr %r0
seg000:00101B44 90 01 00 08 stw %r0, arg_8(%sp)
seg000:00101B48 94 21 FF C0 stwu %sp, -0x40(%sp)
seg000:00101B4C 48 01 6B 39 bl check2
seg000:00101B50 60 00 00 00 nop
seg000:00101B54 80 01 00 48 lwz %r0, 0x40+arg_8(%sp)
seg000:00101B58 38 21 00 40 addi %sp, %sp, 0x40
seg000:00101B5C 7C 08 03 A6 mtlr %r0
seg000:00101B60 4E 80 00 20 blr
seg000:00101B64 # End of function check1
```

As you can see in IDA, that function is called from many places in the program, but only the r3 register’s value is checked after each call.

All this function does is to call the other function, so it is a thunk function: there are function prologue and epilogue, but the r3 register is not touched, so check1() returns what check2() returns.

BLR looks like the return from the function, but since IDA does the function layout, we probably do not need to care about this.

Since it is a typical RISC, it seems that subroutines are called using a link register, just like in ARM.

The `check2()` function is more complex:

```assembly
seg000:00118684 check2: # CODE XREF: check1+Cp
seg000:00118684
seg000:00118684 .set var_18, -0x18
seg000:00118684 .set var_C, -0xC
seg000:00118684 .set var_8, -8
seg000:00118684 .set var_4, -4
seg000:00118684 .set arg_8, 8
seg000:00118684
seg000:00118684 93 E1 FF FC stw %r31, var_4(%sp)
seg000:00118688 7C 08 02 A6 mflr %r0
```

---

13(PowerPC) Branch to Link Register

(For statistics collecting purposes) if you’ve read this far, please click [here](http://example.com). Thanks!
We are lucky again: some function names are left in the executable (debug symbols section? eventually these functions call other functions with names like seg000, so these are clearly dealing with an USB device.

Eventually these functions call other functions with names like .RBEFINDNEXT() and .RBEFINDFIRST(). Eventually these functions call other functions with names like .GetNextDeviceViaUSB(), .USBSendPKT(), so these are clearly dealing with an USB device.

There is even a function named .GetNextEve3Device()—sounds familiar, there was a Sentinel Eve3 dongle for ADB port (present on Macs) in 1990s.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s first take a look on how the r3 register is set before return, while ignoring everything else.

We know that a “good” r3 value has to be non-zero, zero r3 leads the execution flow to the message box with an error message.

There are two li %r3, 1 instructions present in the function and one li %r3, 0 (Load Immediate, i.e., loading a value into a register). The first instruction is at 0x001186B0—and frankly speaking, it’s hard to say what it means.

What we see next is, however, easier to understand: .RBEFINDFIRST() is called: if it fails, 0 is written into r3 and we jump to exit, otherwise another function is called (check3())—if it fails too. .RBEFINDNEXT() is called, probably in order to look for another USB device.

N.B.: clrlwi. %r0, %r3, 16 it is analogical to what we already saw, but it clears 16 bits, i.e., .RBEFINDFIRST() probably returns a 16-bit value.

B (stands for branch) unconditional jump.

BEQ is the inverse instruction of BNE.

Let’s see check3():

```
seg000:0011873C  check3:  # CODE XREF: check2+88p
seg000:0011873C  .set var_18, -0x18

There are a lot of calls to .RBEREAD().

Perhaps, the function returns some values from the dongle, so they are compared here with some hard-coded variables using CMPLWI.

We also see that the r3 register is also filled before each call to .RBEREAD() with one of these values: 0, 1, 8, 0xA, 0xB, 0xC, 0xD, 4, 5. Probably a memory address or something like that?

Yes, indeed, by googling these function names it is easy to find the Sentinel Eve3 dongle manual!

Perhaps we don’t even have to learn any other PowerPC instructions: all this function does is just call .RBEREAD(), compare its results with the constants and returns 1 if the comparisons are fine or 0 otherwise.

OK, all we’ve got is that check1() has always to return 1 or any other non-zero value.

But since we are not very confident in our knowledge of PowerPC instructions, we are going to be careful: we will patch the jumps in check2() at 0x001186FC and 0x00118718.

At 0x001186FC we’ll write bytes 0x48 and 0 thus converting the BEQ instruction in an B (unconditional jump): we can spot its opcode in the code without even referring to [PowerPC(tm) Microprocessor Family: The Programming Environments for 32-Bit Microprocessors, (2000)]14.

At 0x00118718 we’ll write 0x60 and 3 zero bytes, thus converting it to a NOP instruction: Its opcode we could spot in the code too.

And now it all works without a dongle connected.

In summary, such small modifications can be done with IDA and minimal assembly language knowledge.

8.5.2 Example #2: SCO OpenServer

An ancient software for SCO OpenServer from 1997 developed by a company that disappeared a long time ago.

There is a special dongle driver to be installed in the system, that contains the following text strings:
“Copyright 1989, Rainbow Technologies, Inc., Irvine, CA” and “Sentinel Integrated Driver Ver. 3.0 “.

14Also available as http://yurichev.com/mirrors/PowerPC/6xx_pem.pdf

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
After the installation of the driver in SCO OpenServer, these device files appear in the /dev filesystem:

/dev/rbsl8
/dev/rbsl9
/dev/rbsl10

The program reports an error without dongle connected, but the error string cannot be found in the executables.

Thanks to IDA, it is easy to load the COFF executable used in SCO OpenServer.

Let's also try to find “rbsl” string and indeed, found it in this code fragment:

```

Yes, indeed, the program needs to communicate with the driver somehow.

The only place where the SSQC() function is called is the thunk function:

SSQ() can be called from at least 2 functions. One of these is:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
"3C" and "3E" sound familiar: there was a Sentinel Pro dongle by Rainbow with no memory, providing only one crypto-hashing secret function.

You can read a short description of what hash function is here: 2.11 on page 472.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
But let's get back to the program.

So the program can only check the presence or absence of a connected dongle.

No other information can be written to such dongle, as it has no memory. The two-character codes are commands (we can see how the commands are handled in the SSQC() function) and all other strings are hashed inside the dongle, being transformed into a 16-bit number. The algorithm was secret, so it was not possible to write a driver replacement or to remake the dongle hardware that would emulate it perfectly.

However, it is always possible to intercept all accesses to it and to find what constants the hash function results are compared to.

But we need to say that it is possible to build a robust software copy protection scheme based on secret cryptographic hash-function: let it encrypt/decrypt the data files your software uses.

But let's get back to the code.

Codes 51/52/53 are used for LPT printer port selection. 3x/4x are used for “family” selection (that’s how Sentinel Pro dongles are differentiated from each other: more than one dongle can be connected to a LPT port).

The only non-2-character string passed to the hashing function is “0123456789”.

Then, the result is compared against the set of valid results.

If it is correct, 0xC or 0xB is to be written into the global variable ctl_model.

Another text string that gets passed is “PRESS ANY KEY TO CONTINUE: ”, but the result is not checked. Hard to say why, probably by mistake.

Let's see where the value from the global variable ctl_model is used.

One such place is:

```
.text:0000D708 prep_sys proc near ; CODE XREF: init_sys+46Ap
.text:0000D708
.text:0000D708 var_14 = dword ptr -14h
.text:0000D708 var_10 = byte ptr -10h
.text:0000D708 var_8 = dword ptr -8h
.text:0000D708 var_2 = word ptr -2h
.text:0000D708
.text:0000D708 push ebp
.text:0000D709 mov eax, ds:net_env
.text:0000D70E mov ebp, esp
.text:0000D710 sub esp, 1Ch
.text:0000D713 test eax, eax
.text:0000D715 jnz short loc_D734
.text:0000D717 mov al, ds:ctl_model
.text:0000D71C test al, al
.text:0000D71E jnz short loc_D77E
.text:0000D720 mov [ebp+var_8], offset aIeCvulnv0kgT_; "Ie-cvulnv\\bOKG\]T_"
.text:0000D727 mov edx, 7
.text:0000D72C jmp loc_D7E7
 ...
```

If it is 0, an encrypted error message is passed to a decryption routine and printed.

The error string decryption routine seems a simple xorring:

```
15What a strange feeling: to find bugs in such ancient software.
```
That’s why we were unable to find the error messages in the executable files, because they are encrypted (which is is popular practice).

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Another call to the SSQ() hashing function passes the “offln” string to it and compares the result with 0xFE81 and 0x12A9.

If they don’t match, it works with some timer() function (maybe waiting for a poorly connected dongle to be reconnected and check again?) and then decrypts another error message to dump.

```
.text:0000DA55 loc_DA55:       ; CODE XREF: sync_sys+24Cj

.text:0000DABA              mov   [ebp+var_18], 1
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Bypassing the dongle is pretty straightforward: just patch all jumps after the relevant CMP instructions. Another option is to write our own SCO OpenServer driver, containing a table of questions and answers, all of those which present in the program.

Decrypting error messages

By the way, we can also try to decrypt all error messages. The algorithm that is located in the err_warn() function is very simple, indeed:

Listing 8.3: Decryption function

```assembly
.text:0000A44D  mov    esi, [ebp+arg_C] ; key
.text:0000A450  mov    edx, [ebp+arg_4] ; string
.text:0000A453  loc_A453:
.text:0000A453  xor    eax, eax
.text:0000A455  mov    al, [edx+edi] ; load encrypted byte
.text:0000A458  xor    eax, esi ; decrypt it
.text:0000A45A  add    esi, 3 ; change key for the next byte
.text:0000A45D  inc    edi
.text:0000A45E  cmp    edi, ecx
.text:0000A460  mov    [ebp+edi+var_55], al
.text:0000A464  jl     short loc_A453
```

As we can see, not just string is supplied to the decryption function, but also the key:

```assembly
.text:0000DAF7  error:
.text:0000DAF7  ; CODE XREF: sync_sys+255j
.text:0000DAF7  ; sync_sys+274j ...
.text:0000DAF7  mov    [ebp+var_8], offset encrypted_error_message2
.text:0000DAFE  mov    [ebp+var_C], 17h ; decrypting key
.text:0000DB05  jmp    decrypt_end_print_message
```

The algorithm is a simple xorring: each byte is xored with a key, but the key is increased by 3 after the processing of each byte.

We can write a simple Python script to check our hypothesis:

Listing 8.4: Python 3.x

```python
#!/usr/bin/python

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
```
import sys
msg=[0x74, 0x72, 0x78, 0x43, 0x48, 0x6, 0x5A, 0x49, 0x4C, 0x47, 0x47, 0x51, 0x4F, 0x47, 0x61, 0x20, 0x22, 0x3C, 0x24, 0x36, 0x76, 0x3A, 0x33, 0x31, 0x0C, 0x0B, 0x1F, 0x7, 0x1E, 0x1A]
key=0x17
tmp=key
for i in msg:
sys.stdout.write (%c % (i^tmp))
tmp=tmp+3
sys.stdout.flush()
And it prints: “check security device connection”. So yes, this is the decrypted message.

There are also other encrypted messages with their corresponding keys. But needless to say, it is possible to decrypt them without their keys. First, we can see that the key is in fact a byte. It is because the core decryption instruction (XOR) works on byte level. The key is located in the ESI register, but only one byte part of ESI is used. Hence, a key may be greater than 255, but its value is always to be rounded.

As a consequence, we can just try brute-force, trying all possible keys in the 0..255 range. We are also going to skip the messages that has unprintable characters.

Listing 8.5: Python 3.x

#!/usr/bin/python
import sys, curses.ascii
msgs=[
[0x74, 0x72, 0x78, 0x43, 0x48, 0x6, 0x5A, 0x49, 0x4C, 0x47, 0x47, 0x51, 0x4F, 0x47, 0x61, 0x20, 0x22, 0x3C, 0x24, 0x36, 0x76, 0x3A, 0x33, 0x31, 0x0C, 0x0B, 0x1F, 0x7, 0x1E, 0x1A],
[0x49, 0x65, 0x2D, 0x63, 0x76, 0x75, 0x6C, 0x6E, 0x76, 0x56, 0x5C, 8, 0x4F, 0x4B, 0x47, 0x5D, 0x54, 0x5F, 0x1D, 0x26, 0x2C, 0x33, 0x27, 0x2B, 0x76, 0x72, 0x75, 0x78, 0x7E, 0x41, 0x44],

[0x72, 0x7C, 0x72, 0x79, 0x76, 0x0, 0x50, 0x43, 0x4A, 0x59, 0x5D, 0x5B, 0x41, 0x41, 0x1B, 0x5A, 0x24, 0x32, 0x2E, 0x29, 0x28, 0x70, 0x20, 0x22, 0x38, 0x28, 0x36, 0x0D, 0x0B, 0x48, 0x4B, 0x4E]]
def is_string_printable(s):
    return all(list(map(lambda x: curses.ascii.isprint(x), s)))
cnt=1
for msg in msgs:
    print ("message %d" % cnt)
    for key in range(0,256):
        tmp=key
        for i in msg:
            result.append (i^tmp)
            tmp=tmp+3
        if is_string_printable (result):
            print ("key=", key, "value=", ".join(list(map(chr, result))))
cnt=cnt+1
And we get:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There is some garbage, but we can quickly find the English-language messages!

By the way, since the algorithm is a simple xoring encryption, the very same function can be used to encrypt messages. If needed, we can encrypt our own messages, and patch the program by inserting them.

### 8.5.3 Example #3: MS-DOS

Another very old software for MS-DOS from 1995 also developed by a company that disappeared a long time ago.

In the pre-DOS extenders era, all the software for MS-DOS mostly relied on 16-bit 8086 or 80286 CPUs, so the code was 16-bit en masse.

The 16-bit code is mostly same as you already saw in this book, but all registers are 16-bit and there are less instructions available.

The MS-DOS environment has no system drivers, and any program can deal with the bare hardware via ports, so here you can see the OUT/IN instructions, which are present in mostly in drivers in our times (it is impossible to access ports directly in user mode on all modern OSes).

Given that, the MS-DOS program which works with a dongle has to access the LPT printer port directly.

So we can just search for such instructions. And yes, here they are:

```assembly
seg030:0034        out_port proc far ; CODE XREF: sent_pro+22p
seg030:0034
seg030:0034
seg030:0034     arg_0 = byte ptr 6
seg030:0034
seg030:0034     55
seg030:0034     push bp
seg030:0034     8B EC
seg030:0034     mov bp, sp
seg030:0034     8B 16 7E E7
seg030:0034     mov dx, _out_port ; 0x378
seg030:0034     8A 46 06
seg030:0034     mov al, [bp+arg_0]
seg030:0034     83C3 EE
seg030:0034     out dx, al
seg030:0034     8D 0F 5D
seg030:0034     pop bp
seg030:0034     8904 CB
seg030:0034     retf
seg030:0040        out_port endp
```

(All label names in this example were given by me).

`out_port()` is referenced only in one function:

```assembly
seg030:0041        sent_pro proc far ; CODE XREF: check_dongle+34p
seg030:0041
seg030:0041     var_3 = byte ptr -3
```

This is again a Sentinel Pro “hashing” dongle as in the previous example. It is noticeably because text strings are passed here, too, and 16 bit values are returned and compared with others.

So that is how Sentinel Pro is accessed via ports.

The output port address is usually 0x378, i.e., the printer port, where the data to the old printers in pre-USB era was passed to.

The port is uni-directional, because when it was developed, no one imagined that someone will need to transfer information from the printer. 16

The only way to get information from the printer is a status register on port 0x379, which contains such bits as “paper out”, “ack”, “busy”—thus the printer may signal to the host computer if it is ready or not and if paper is present in it.

So the dongle returns information from one of these bits, one bit at each iteration.

_ in_port_ 2 contains the address of the status word (0x379) and _ in_port_ 1 contains the control register address (0x37A).

It seems that the dongle returns information via the “busy” flag at seg030:00B9: each bit is stored in the DI register, which is returned at the end of the function.

What do all these bytes sent to output port mean? Hard to say. Perhaps, commands to the dongle.

But generally speaking, it is not necessary to know: it is easy to solve our task without that knowledge.

Here is the dongle checking routine:

```
seg030:0145 check_dongle proc far ; CODE XREF: sub_3771D+3EP

16If we consider Centronics only. The following IEEE 1284 standard allows the transfer of information from the printer.
And this is how the main dongle checking function is called:

The text strings seem to be constructed randomly as well, during software development. Compared with the correct value.

So the text string is selected randomly, passed into the dongle, and then the result of the hashing is biostime().

Since the routine can be called very frequently, e.g., before the execution of each important software feature, and accessing the dongle is generally slow (because of the slow printer port and also slow MCU in the dongle), they probably added a way to skip some dongle checks, by checking the current time in the biostime() function.

The get_rand() function uses the standard C function:

So the text string is selected randomly, passed into the dongle, and then the result of the hashing is compared with the correct value.

The text strings seem to be constructed randomly as well, during software development.

And this is how the main dongle checking function is called:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Bypassing the dongle is easy, just force the check_dongle() function to always return 0.

For example, by inserting this code at its beginning:

```
mov ax,0
retf
```

The observant reader might recall that the strcpy() C function usually requires two pointers in its arguments, but we see that 4 values are passed:

```
seg033:088F 1E                push  ds
seg033:0890 68 22 44          push  offset aTrupcRequiresA ;
"This Software Requires a Software Lock\n"
seg033:0893 1E                push  ds
seg033:0894 68 60 E9          push  offset byte_6C7E0 ; dest
seg033:0897 9A 79 65 00+      call  _strcpy
seg033:089C 83 C4 08          add   sp, 8
seg033:089E 1E                push  ds
seg033:08A0 68 42 44          push  offset aPleaseContactA ; "Please Contact ..."
seg033:08A3 1E                push  ds
seg033:08A4 68 60 E9          push  offset byte_6C7E0 ; dest
seg033:08A7 9A CD 64 00+      call  _strcat
```

This is related to MS-DOS’ memory model. You can read more about it here: 11.6 on page 976.

So as you may see, strcpy() and any other function that take pointer(s) in arguments work with 16-bit pairs.

Let’s get back to our example. DS is currently set to the data segment located in the executable, that is where the text string is stored.

In the `sent_pro()` function, each byte of the string is loaded at `seg030:00EF`: the LES instruction loads the ES:BX pair simultaneously from the passed argument.

The MOV at `seg030:00F5` loads the byte from the memory at which the ES:BX pair points.

### 8.6 Encrypted database case #1

(This part has been first appeared in my blog at 26-Aug-2015. Some discussion: https://news.ycombinator.com/item?id=10128684.)

#### 8.6.1 Base64 and entropy

I’ve got the XML file containing some encrypted data. Perhaps, it’s related to some orders and/or customers information.

```
<Orders>
  <Order>
    <OrderID>1</OrderID>
    <Data>yjmxhXUbhB/5MV45chPsXZWAJwIh1S0aD9lFn3xJMSxJ3/E+UE3hsnH</Data>
  </Order>
  <Order>
    <OrderID>2</OrderID>
    <Data>0KGe/wnypFbjsy+U0C2P9fC5nDZP3XDZLMPCraIw90joy1k6Tu5U=</Data>
  </Order>
</Orders>
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This is clearly base64-encoded data, because all strings consisting of Latin characters, digits, plus (+) and slash (/) symbols. There can be 1 or 2 padding symbols (=), but they are never occurred in the middle of string. Keeping in mind these base64 properties, it's very easy to recognize them.

Let's decode them and calculate entropies (9.2 on page 920) of these blocks in Wolfram Mathematica:

```mathematica
In[1]:= ListOfBase64Strings = 
    Map[First[#[[3]]] &, Cases[Import["encrypted.xml"], XMLElement["Data", _, _, Infinity]]];

In[2]:= BinaryStrings = 
    Map[ImportString[#, {"Base64", "String"}] &, ListOfBase64Strings];

In[3]:= Entropies = Map[N[Entropy[2, #]] &, BinaryStrings];

In[4]:= Variance[Entropies] 
Out[4]= 0.0238614
```

Variance is low. This means the entropy values are not very different from each other. This is visible on graph:

```mathematica
In[5]:= ListPlot[Entropies]
```

Most values are between 5.0 and 5.4. This is a sign that the data is compressed and/or encrypted.

To understand variance, let's calculate entropies of all lines in Conan Doyle’s *The Hound of the Baskervilles* book:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Most values are gathered around value of 4, but there are also values which are smaller, and they are influenced final variance value.

Perhaps, shortest strings has smaller entropy, let’s take short string from the Conan Doyle’s book:

```
In[] := Entropy[2, "Yes, sir."] // N
Out[] = 2.9477
```

Let’s try even shorter:

```
In[] := Entropy[2, "Yes"] // N
Out[] = 1.58496

In[] := Entropy[2, "No"] // N
Out[] = 1.
```

8.6.2 Is data compressed?

OK, so our data is compressed and/or encrypted. Is it compressed? Almost all data compressors put some header at the start, signature, or something like that. As we can see, there are no consistent data at the start of each block. It’s still possible that this is a handmade data compressor, but they are very rare. On the other hand, handmade cryptoalgorithms are much more popular, because it’s very easy to make it work. Even primitive keyless cryptosystems like \texttt{memfrob}\footnote{http://linux.die.net/man/3/memfrob} and ROT13 works fine without errors. It’s
a serious challenge to write data compressor from scratch using only fantasy and imagination in a way so it will have no evident bugs. Some programmers implements data compression functions by reading textbooks, but this is also rare. The most popular two ways are: 1) just take open-source library like zlib; 2) copy & paste something from somewhere. Open-source data compressions algorithms usually puts some kind of header, and so do algorithms from sites like http://www.codeproject.com/.

8.6.3 Is data encrypted?

Major data encryption algorithms process data in blocks. DES—8 bytes, AES—16 bytes. If the input buffer is not divided evenly by block size, it’s padded by zeroes (or something else), so encrypted data will be aligned by cryptoalgorithm’s block size. This is not our case.

Using Wolfram Mathematica, I analyzed block’s lengths:

\[
\text{In[] := Counts[Map[StringLength[#] & , BinaryStrings]]}
\]

\[
\]

1858 blocks has size of 42 bytes, 1235 blocks has size of 38 bytes, etc.

I made a graph:

\[
\text{ListPlot[Counts[Map[StringLength[#] & , BinaryStrings]]]}
\]

So, most blocks has size between ~36 and ~48. There is also another thing to notice: all block sizes are even. No single block with odd size.

There are, however, stream ciphers which can operate on byte level or even on bit level.

8.6.4 CryptoPP

The program which can browse this encrypted database is written C# and the .NET code is heavily obfuscated. Nevertheless, there is DLL with x86 code, which, after brief examination, has parts of the CryptoPP
popular open-source library! (I just spotted “CryptoPP” strings inside.) Now it’s very easy to find all functions inside of DLL because CryptoPP library is open-source.

CryptoPP library has a lot of crypto-functions, including AES (AKA Rijndael). Newer x86 CPUs has AES helper instructions like AESENC, AESDEC and AESKEYGENASSIST ¹⁸. They are not performing encryption/decryption completely, but they do significant amount of job. And newer CryptoPP versions use them. For example, here: ¹, ². To my surprise, during decryption, AESENC gets executed, while AESDEC is not (I just checked with my tracer utility, but any debugger can be used). I checked, if my CPU really supports AES instructions. Some Intel i3 CPUs are not. And if not, CryptoPP library falling back to AES functions implemented in old way ¹⁹. But my CPU supports them. Why AESDEC is still not executed? Why the program use AES encryption in order to decrypt database?

OK, it’s not a problem to find a function which encrypts block. It is called CryptoPP::Rijndael::Enc::ProcessAndXorBlock() src, and it can call another function: Rijndael::Enc::AdvancedProcessBlocks() src, which, in turn, can call two other functions ( AESNI_Enc_Block and AESNI_Enc_4_Blocks ) which has AESENC instructions.

So, judging by CryptoPP internals, CryptoPP::Rijndael::Enc::ProcessAndXorBlock() encrypts one 16-byte block. Let’s set breakpoint on it and see, what happens during decryption. I use my simple tracer tool again. The software must decrypt first data block now. Oh, by the way, here is the first data block converted from base64 encoding to hexadecimal data, let’s have it at hand:

```
00000000: CA 39 B1 85 75 1B 84 1F F9 31 5E 39 72 13 EC 5D ..9..u....1^9r..
00000010: 95 80 27 02 21 D5 2D 1A 0F D9 45 9F 75 EE 24 C4 ..'!.-...E.u.$.
00000020: B1 27 7F 84 FE 41 37 86 C9 C0 .'...A7...
```

These are also arguments of the function from CryptoPP source files:

```
size_t Rijndael::Enc::AdvancedProcessBlocks(const byte *inBlocks, const byte *xorBlocks, byte *outBlocks, size_t length, word32 flags);
```

So it has 5 arguments. Possible flags are:

```
enum {BT_InBlockIsCounter=1, BT_DontIncrementInOutPointers=2, BT_XorInput=4, BT_ReverseDirection=8, BT_AllowParallel=16} FlagsForAdvancedProcessBlocks;
```

OK, run tracer on ProcessAndXorBlock() function:

```
... tracer.exe -l:filename.exe bpf=filename.exe!0x4339a0,args:5,dump_args:0x10
```

Warning: no tracer.cfg file.

Argument 3/5 difference
```
```
00000000: C7 39 4E 7B 33 1B D6 1F-B8 31 10 39 39 13 A5 5D ".9N{3....1.99...}"
(0) software.exe!0x4339a0(0x38a828, 0x38a838, 0x38bb40, 0x0, 0x8) (called from software.exe!.text+0x3a407 (0x13eb407))
```

For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here we can see inputs to the ProcessAndXorBlock() function, and outputs from it.
This is output from the function during first call:

00000000: C7 39 4E 7B 33 1B D6 1F-B8 31 10 39 39 13 A5 5D ".9N{3....1.99..}"

Then the ProcessAndXorBlock() is called with zero-length block, but with 8 flag (BT_ReverseDirection).
Second call:

00000000: 45 00 20 00 4A 00 4F 00-48 00 4E 00 53 00 00 00 "E. .J.O.H.N.S..."

Wow, there is some string familiar to us!
Third call:

00000000: B1 27 7F E4 9F 01 E3 81-CF C6 12 FB B9 7C F1 BC ".'............|.."

The first output is very similar to the first 16 bytes of the encrypted buffer.
Output of the first call of ProcessAndXorBlock():

00000000: C7 39 4E 7B 33 1B D6 1F-B8 31 10 39 39 13 A5 5D ".9N{3....1.99..}"

First 16 bytes of encrypted buffer:

00000000: CA 39 B1 85 75 1B 84 1F-F9 31 5E 39 72 13 EC 5D .9...u....1^9r...]

There are too much equal bytes! How come AES encryption result can be very similar to the encrypted buffer while this is not encryption but rather decryption?!

8.6.5 Cipher Feedback mode

The answer is CFB\(^{20}\): in this mode, AES algorithm used not as encryption algorithm, but as a device which generates cryptographically secure random data. The actual encryption is happening using simple XOR operation.
Here is encryption algorithm (images are taken from Wikipedia):

\(^{20}\)Cipher Feedback
And decryption:

Now let’s see: AES encryption operation generates 16 bytes (or 128 bits) of random data to be used while XOR-ing, who forces us to use all 16 bytes? If at the last iteration we’ve got 1 byte of data, let’s xor 1 byte of data with 1 byte of generated random data? This leads to important property of CFB mode: data can be not padded, data of arbitrary size can be encrypted and decrypted.

Oh, that’s why all encrypted blocks are not padded. And that’s why AESDEC instruction is never called.

Let’s try to decrypt first block manually, using Python. CFB mode also use IV, as a seed for CSPRNG\(^\text{21}\). In our case, IV is the block which is encrypted at first iteration:

\[
\begin{array}{c}
0038B920: 01 00 00 00 FF FF FF 79 C1 69 0B 67 C1 04 7D “........y.i.g..”
\end{array}
\]

Oh, and we also have to recover encryption key. There is AESKEYGENASSIST is DLL, and it is called, and it is used in the Rijndael::Base::UncheckedSetKey() function: src. It’s easy to find it in IDA and set breakpoint. Let’s see:

```
... tracer.exe -l:filename.exe bpf=filename.exe!0x435c30,args:3,dump_args:0x10
```

Warning: no tracer.cfg file.
PID=2068|New process software.exe
no module registered with image base 0x77320000
no module registered with image base 0x76e20000
no module registered with image base 0x77320000

\(^{21}\text{Cryptographically Secure Pseudorandom Number Generator}\)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
no module registered with image base 0x77220000
Warning: unknown (to us) INT3 breakpoint at ntdll.dll!LdrVerifyImageMatchesChecksum+0x96c (0
⤦ x776c103b)
(0) software.exe!0x435c30(0x15e8000, 0x10, 0x14f808) (called from software.exe!.text+0x22fa1 (0
⤦ x13d3fa1))
Argument 1/3
015E8000: CD C5 7E AD 28 5F 6D E1-CE 8F CC 29 B1 21 88 8E "..~.(._m....).!.."
Argument 3/3
0014F808: 38 82 58 01 C8 B9 46 00-01 D1 3C 01 00 F8 14 00 "B.X...F...<......"
Argument 3/3 +0x8: software.exe!.rdata+0x5238
Argument 3/3 +0x8: software.exe!.text+0x1c101
(0) software.exe!0x435c30() -> 0x13c2801
PID=2068|Process software.exe exited. ExitCode=0 (0x0)

So this is the key: CD C5 7E AD 28 5F 6D E1-CE 8F CC 29 B1 21 88 8E.

During manual decryption we’ve got this:

<table>
<thead>
<tr>
<th>Argument 1/3</th>
<th>Argument 3/3</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000: 0D 00 FF FE 46 00 52 00 41 00 4E 00 48 00 49 00</td>
<td>00000000: 38 82 58 01 C8 B9 46 00-01 D1 3C 01 00 F8 14 00</td>
</tr>
<tr>
<td>Argument 3/3 +0x0: software.exe!.rdata+0x5238</td>
<td>Argument 3/3 +0x8: software.exe!.text+0x1c101</td>
</tr>
<tr>
<td>00000020: 66 66 66 9E 61 40 D4 07 06 01</td>
<td>PID=2068</td>
</tr>
</tbody>
</table>

Now this is something readable! And now we can see why there were so many equal bytes at the first decryption iteration: because plaintext has so many zero bytes!

Let’s decrypt the second block:

<table>
<thead>
<tr>
<th>Argument 1/3</th>
<th>Argument 3/3</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000: 17 98 D0 84 3A E9 72 4F DB 82 3F AD E9 3E 2A A8</td>
<td>00000000: 41 00 52 00 52 00 4F 00 4E 00 4D CC CC CC CC</td>
</tr>
<tr>
<td>00000020: D4 07 06 01</td>
<td>A.R.R.O.N. ....</td>
</tr>
<tr>
<td>00000000: 5D 90 59 06 EF F4 96 B4 7C 3A A7 4J BE FF 66 AB</td>
<td>00000000: 04 0D 06 01</td>
</tr>
<tr>
<td>00000010: 49 00 47 00 47 00 53 00 00 00 00 00 C0 65 40</td>
<td>I.G.G.S. ....@.</td>
</tr>
<tr>
<td>A.R.C.U.S....</td>
<td></td>
</tr>
</tbody>
</table>
| 00000020: 66 40 D4 07 06 01 | Y.H.z...h@

All blocks decrypted seems correct except of first 16 bytes part.

8.6.6 Initializing Vector

What can affect first 16 bytes?

Let’s back to CFB decryption algorithm again: 8.6.5 on the previous page.

We can see that IV can affect to first block decryption operation, but not the second, because during the second iteration, ciphertext from the first iteration is used, and in case of decryption, it’s the same, no matter what IV has!

So probably, IV is different each time. Using my tracer, I’ll take a look at the first input during decryption of the second block of XML file:

<table>
<thead>
<tr>
<th>Argument 1/3</th>
<th>Argument 3/3</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000: 02 00 00 00 FE FF FF FF-FF-79 C1 69 0B 67 C1 04 7D</td>
<td>00000000: 02 00 00 00 FE FF FF FF-FF-79 C1 69 0B 67 C1 04 7D</td>
</tr>
<tr>
<td>&quot;........y.i.g.&quot;)</td>
<td>&quot;........y.i.g.&quot;)</td>
</tr>
</tbody>
</table>
| 00000020: 03 00 00 00 FD FF FF FF-FF-79 C1 69 0B 67 C1 04 7D |...third:
| 00000020: 38 82 58 01 C8 B9 46 00-01 D1 3C 01 00 F8 14 00 |
| 00000000: 04 0D 06 01 | 00000000: 04 0D 06 01 |
| 00000010: 49 00 47 00 47 00 53 00 00 00 00 00 C0 65 40 | 00000000: 04 0D 06 01 |
| I.G.G.S. ....@.|
| 00000020: 66 40 D4 07 06 03 | Y.H.z...h@

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
It seems, first and fifth byte are changed each time. I finally concluded that the first 32-bit integer is just OrderID from the XML file, and the second 32-bit integer is also OrderID, but negated. All other 8 bytes are same for each operation. Now I have decrypted the whole database: https://raw.githubusercontent.com/DennisYurichev/RE-for-beginners/master/examples/encrypted_DB1/decrypted.full.txt.

The Python script used for this is: https://github.com/DennisYurichev/RE-for-beginners/blob/master/examples/encrypted_DB1/decrypt_blocks.py.

Perhaps, the author wanted each block encrypted differently, so he/she used OrderID as part of key. It would be also possible to make different AES key instead of IV.

So now we know that IV only affects first block during decryption in CFB mode, this is feature of it. All other blocks can be decrypted without knowledge IV, but using the key.

OK, so why CFB mode? Apparently, because the very first AES example on CryptoPP wiki uses CFB mode: http://www.cryptopp.com/wiki/Advanced_Encryption_Standard#Encrypting_and_Decrypting_Using_AES. Supposedly, developer choose it for simplicity: the example can encrypt/decrypt text strings with arbitrary lengths, without padding.

It is very likely, program’s author(s) just copypasted the example from CryptoPP wiki page. Many programmers do so.

The only difference that IV is chosen randomly in CryptoPP wiki example, while this indeterminism wasn’t allowable to programmers of the software we are dissecting now, so they choose to initialize IV using Order ID.

Now we can proceed to analyzing matter of each byte in the decrypted block.

### 8.6.7 Structure of the buffer

Let’s take first four decrypted blocks:

| 00000000: | 0D 00 FF FE 46 00 52 00 | 01 00 4E 00 4B 00 49 00 | ....F.R.A.N.K.I. |
| 00000010: | 45 00 20 00 4A 00 4F 00 | 48 00 4E 00 53 00 66 66 |  E.J.O.H.N.S.ff |
| 00000020: | 66 66 66 9E 61 40 D4 07 | 06 01 | fff.a@.... |

| 00000000: | 08 00 FF FE 4C 00 4F 00 | 52 00 49 00 20 00 42 00 | ....L.O.R.I. .B. |
| 00000010: | 41 00 52 00 52 00 4F 00 | 4E 00 CD CC CC CC CC | A.R.R.O.N...... |
| 00000020: | 18 40 D4 07 06 01 | .@.... |

| 00000000: | 0A 00 FF FE 47 00 41 00 | 52 00 59 00 20 00 42 00 | ....G.A.R.Y. .B. |
| 00000010: | 49 00 47 00 47 00 53 00 | 00 00 00 00 00 C0 65 40 | I.G.G.S......@ |
| 00000020: | D4 07 06 01 | .... |

| 00000000: | 0F 00 FF FE 4D 00 45 00 | 4C 00 49 00 4E 00 44 00 | ....M.E.L.I.N.D. |
| 00000010: | 41 00 20 00 44 00 4F 00 | 48 00 45 00 52 00 54 00 | A.D.O.H.E.R.T. |
| 00000020: | 59 00 48 E1 7A 14 AE FF | 68 40 D4 07 06 02 | Y.H.z...h@.... |

UTF-16 encoded text strings are clearly visible, these are names and surnames. The first byte (or 16-bit word) is seems string length, we can visually check it. FF FE is seems Unicode BOM.

There are 12 more bytes after each string.

Using this script (https://github.com/DennisYurichev/RE-for-beginners/blob/master/examples/encrypted_DB1/dump_buffer_rest.py) I’ve got random selection of the tails:

dennis@...:$ python decrypt.py encrypted.xml | shuf | head -20

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We first see the 0x40 and 0x07 bytes present in each tail. The very last byte is always in 1..0x1F (1..31) range, I've checked. The penultimate byte is always in 1..0xC (1..12) range. Wow, that looks like a date! Year can be represented as 16-bit value, and maybe last 4 bytes is date (16 bits for year, 8 bits for month and 8 more for day)? 0x7DDD is 2013, 0x7D5D is 2005, etc. Seems fine. This is a date. There are 8 more bytes. Judging by the fact this is database named orders, maybe some kind of sum is present here? I made attempt to interpret it as double-precision IEEE 754 floating point and dump all values!

Some are:

71.0
134.0
51.95
53.0
121.99
96.95
98.95
85.95
184.99
94.95
29.95
85.0
36.0
130.99
115.95
87.99
127.95
114.0
150.95

Looks like real!

Now we can dump names, sums and dates.

plain:
00000000: 00 00 FF FE 46 00 52 00 41 00 4E 00 4B 00 49 00 ....F.R.A.N.K.I.

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
This is some kind of OOP serialization, i.e., packing differently typed values into binary buffer for storing and/or transmitting.

### 8.6.8 Noise at the end

The only question remaining is that sometimes, tail is bigger:

```plaintext
OrderID= 5 name= LENA MARCUS sum= 179.0 date= 2004 / 6 / 3

```

This is some kind of OOP serialization, i.e., packing differently typed values into binary buffer for storing and/or transmitting.

### 8.6.8 Noise at the end

The only question remaining is that sometimes, tail is bigger:

```plaintext
OrderID= 5 name= LENA MARCUS sum= 179.0 date= 2004 / 6 / 3
```

(00 07 19 bytes are not used and is ballast.)

```plaintext
OrderID= 172 name= THERESE TUTTLE sum= 152.95 date= 2004 / 7 / 26
```

(00 02 are not used.)

After close examination, we can see, that the noise at the end of tail is just left from previous encryption!

Here are two subsequent buffers:

```plaintext
OrderID= 172 name= THERESE TUTTLE sum= 152.95 date= 2004 / 7 / 26
```

(00 07 19 bytes are copied from the previous plaintext buffer.)

(00 02 are not used.)

Another two subsequent buffers:

```plaintext
OrderID= 285 name= MELANIE KIRK sum= 161.0 date= 2004 / 9 / 2
```

The last 02 byte has been copied from the previous plaintext buffer.

### 8.6.9 Conclusion

Summary: every practicing reverse engineer should be familiar with major crypto algorithms and also major cryptographical modes. Some books about it: 12.1.10 on page 987.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Encrypted database contents has been artificially constructed by me for the sake of demonstration. I’ve got most popular USA names and surnames from there: [http://stackoverflow.com/questions/1803628/raw-list-of-person-names](http://stackoverflow.com/questions/1803628/raw-list-of-person-names), and combined them randomly. Dates and sums were also generated randomly.

All files used in this part are here: [https://github.com/DennisYurichev/RE-for-beginners/tree/master/examples/encrypted_DB1](https://github.com/DennisYurichev/RE-for-beginners/tree/master/examples/encrypted_DB1).

Nevertheless, many features like these I’ve observed in real-world software applications. This example is based on them.

### 8.6.10 Post Scriptum: brute-forcing IV

The case you have just seen has been artificially constructed, but is based on a real application I’ve reverse engineered. When I’ve been working on it, I first noticed that IV has been generating using some 32-bit number, and I wasn’t able to find a link between this value and OrderID. So I prepared to use brute-force, which is indeed possible here.

It’s not a problem to enumerate all 32-bit values and try each as a base for IV. Then you decrypt the first 16-byte block and check for zero bytes, which are always at fixed places.

### 8.7 Overclocking Cointerra Bitcoin miner

There was Cointerra Bitcoin miner, looking like that:

![Image of Cointerra Bitcoin miner](image)

Figure 8.14: Board
And there was also (possibly leaked) utility which can set clock rate for the board. It runs on additional BeagleBone Linux ARM board (small board at bottom of the picture).

And the author was once asked, is it possible to hack this utility to see, which frequency can be set and which are not. And it is possible to tweak it?

The utility must be executed like that: ./cointool-overclock 0 0 900, where 900 is frequency in MHz. If the frequency is too high, utility will print “Error with arguments” and exit.

This is a fragment of code around reference to “Error with arguments” text string:

```assembly

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Function names were present in debugging information of the original binary, like write_power, read_loop. But labels inside functions were named by me.

optind name looks familiar. It is from getopt *NIX library intended for command-line parsing—well, this is exactly what happens inside. Then, the 3rd argument (where frequency value is to be passed) is converted from a string to a number using a call to 

The value is then checked against various constants. At 0xACEC, it's checked, if it is lesser or equal to 499, and if it is so, 0x64 is to be passed to write_power() function (which sends a command through USB using send_msg()). If it is greater than 499, jump to 0xAD08 is occurred.

At 0xAD08 it's checked, if it's lesser or equal to 799. 0x5F is then passed to write_power() function in case of success.

There are more checks: for 899 at 0xAD24, for 0x999 at 0xAD40 and finally, for 1099 at 0xAD5C. If the input frequency is lesser or equal to 1099, 0x50 will be passed (at 0xAD6C) to write_power() function.

And there is some kind of bug. If the value is still greater than 1099, the value itself is passed into write_power() function. Oh, it's not a bug, because we can’t get here: value is checked first against 950 at 0xAC88, and if it is greater, error message will be displayed and the utility will finish.

Now the table between frequency in MHz and value passed to write_power() function:

<table>
<thead>
<tr>
<th>MHz</th>
<th>hexadecimal</th>
<th>decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>499MHz</td>
<td>0x64</td>
<td>100</td>
</tr>
<tr>
<td>799MHz</td>
<td>0x5f</td>
<td>95</td>
</tr>
<tr>
<td>899MHz</td>
<td>0x5a</td>
<td>90</td>
</tr>
<tr>
<td>999MHz</td>
<td>0x55</td>
<td>85</td>
</tr>
<tr>
<td>1099MHz</td>
<td>0x50</td>
<td>80</td>
</tr>
</tbody>
</table>

As it seems, a value passed to the board is gradually decreasing during frequency increasing.

Now we see that value of 950MHz is a hardcoded limit, at least in this utility. Can we trick it?

Let's back to this piece of code:

We must disable BGT branch instruction at 0xAC90 somehow. And this is ARM in ARM mode, because, as we see, all addresses are increasing by 4, i.e., each instruction has size of 4 bytes. NOP (no operation) instruction in ARM mode is just four zero bytes: 00 00 00 00. So by writing four zeros at 0xAC90 address (or physical offset in file 0x2C90) we can disable the check.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now it's possible to set frequencies up to 1050MHz. Even more is possible, but due to the bug, if input value is greater than 1099, a value as is in MHz will be passed to the board, which is incorrect.

I didn’t go further, but if I had to, I would try to decrease a value which is passed to write_power() function.

Now the scary piece of code which I skipped at first:

```
.text:0000AC94 LDR R2, [R11,#third_argument]
.text:0000AC98 MOV R3, #0x51EB851F
.text:0000ACA0 SMULL R1, R3, R3, R2 ; R3=3rg_arg/3.125
.text:0000ACA4 MOV R1, R3, ASR#4 ; R1=R3/16=3rg_arg/50
.text:0000ACA8 MOV R3, R2, ASR#31 ; R3=MSB(3rg_arg)
.text:0000AACAC RSB R3, R3, R1 ; R3=3rd_arg/50
.text:0000ACB0 MOV R1, #50
.text:0000ACB4 MUL R3, R1, R3 ; R3=50*(3rd_arg/50)
.text:0000ACB8 RSB R3, R3, R2
.text:0000ACBC CMP R3, #0
.text:0000ACC0 BEQ loc_ACEC
```

Division via multiplication is used here, and constant is 0x51EB851F. I wrote a simple programmer’s calculator for myself. And I have there a feature to calculate modulo inverse.

```
modinv32(0x51EB851F)
Warning, result is not integer: 3.125000
(unsigned) dec: 3 hex: 0x3 bin: 11
```

That means that SMULL instruction at 0xA9A0 is basically divides 3rd argument by 3.125. In fact, all modinv32() function in my calculator does, is this:

\[
\frac{1}{\text{input}} = \frac{2^{32}}{\text{input}}
\]

Then there are additional shifts and now we see than 3rg argument is just divided by 50. And then it’s multiplied by 50 again. Why? This is simplest check, if the input value is can be divided by 50 evenly. If the value of this expression is non-zero, \(x\) can’t be divided by 50 evenly:

\[
x - \left( \left( \frac{x}{50} \right) \cdot 50 \right)
\]

This is in fact simple way to calculate remainder of division.

And then, if the remainder is non-zero, error message is displayed. So this utility takes frequency values in form like 850, 900, 950, 1000, etc., but not 855 or 911.

That’s it! If you do something like that, please be warned that you may damage your board, just as in case of overclocking other devices like CPUs, GPU\(^{24}\), etc. If you have a Cointerra board, do this on your own risk!

### 8.8 Breaking simple executable cryptor

I’ve got an executable file which is encrypted by relatively simple encryption. Here is it (only executable section is left here).

First, all encryption function does is just adds number of position in buffer to the byte. Here is how this can be encoded in Python:

```
Listing 8.7: Python script
#! /usr/bin/env python
def e(i, k):
    return chr(ord(i)+k % 256)
```

\(^{23}\)https://github.com/DennisYurichev/progcalc

\(^{24}\)Graphics Processing Unit

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
def encrypt(buf):
    return e(buf[0], 0) + e(buf[1], 1) + e(buf[2], 2) + e(buf[3], 3) + e(buf[4], 4) + e(buf[5], 5) +
               e(buf[6], 6) + e(buf[7], 7) +
               e(buf[8], 8) + e(buf[9], 9) + e(buf[10], 10) + e(buf[11], 11) + e(buf[12], 12) + e(buf +
               e(buf[13], 13) + e(buf[14], 14) + e(buf[15], 15)

Hence, if you encrypt buffer with 16 zeros, you'll get 0, 1, 2, 3 ... 12, 13, 14, 15.

Propagating Cipher Block Chaining (PCBC) is also used, here is how it works:

![Diagram of Propagating Cipher Block Chaining (PCBC) mode encryption]

Figure 8.15: Propagating Cipher Block Chaining encryption (image is taken from Wikipedia article)

The problem is that it's too boring to recover IV (Initialization Vector) each time. Brute-force is also not an option, because IV is too long (16 bytes). Let's see, if it's possible to recover IV for arbitrary encrypted executable file?

Let's try simple frequency analysis. This is 32-bit x86 executable code, so let's gather statistics about most frequent bytes and opcodes. I tried huge oracle.exe file from Oracle RDBMS version 11.2 for windows x86 and I've found that the most frequent byte (no surprise) is zero (10%). The next most frequent byte is (again, no surprise) 0xFF (5%). The next is 0x8B (5%).

0x8B is opcode for MOV, this is indeed one of the most busy x86 instructions. Now what about popularity of zero byte? If compiler needs to encode value bigger than 127, it has to use 32-bit displacement instead of 8-bit one, but large values are very rare, so it is padded by zeros. This is at least in LEA, MOV, PUSH, CALL.

For example:

```
8D B0 28 01 00 00       lea    esi, [eax+128h]
8D BF 40 38 00 00       lea    edi, [edi+3840h]
```

Displacements bigger than 127 are very popular, but they are rarely exceeds 0x10000 (indeed, such large memory buffers/structures are also rare).

Same story with MOV, large constants are rare, the most heavily used are 0, 1, 10, 100, $2^n$, and so on. Compiler has to pad small constants by zeros to represent them as 32-bit values:

```
BF 02 00 00 00 00       mov    edi, 2
BF 01 00 00 00 00       mov    edi, 1
```

Now about 00 and FF bytes combined: jumps (including conditional) and calls can pass execution flow forward or backwards, but very often, within the limits of the current executable module. If forward, displacement is not very big and also padded with zeros. If backwards, displacement is represented as negative value, so padded with FF bytes. For example, transfer execution flow forward:

```
E8 43 0C 00 00       call   _function1
E8 5C 00 00 00       call   _function2
0F 84 F0 0A 00 00    jz     \loc\_4F09A0
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Backwards:

E8 79 0C FE FF  call _function1
E8 F4 16 FF FF  call _function2
0F 84 F8 FF FF FF  jz  loc_8212BC
0F 84 06 FD FF FF  jz  loc_FF1E7D

FF byte is also very often occurred in negative displacements like these:

8D 85 1E FF FF FF  lea eax, [ebp-0E2h]
8D 95 F8 5C FF FF  lea edx, [ebp-0A308h]

So far so good. Now we have to try various 16-byte keys, decrypt executable section and measure how often 00, FF and 8B bytes are occurred. Let’s also keep in sight how PCBC decryption works:

Propagating Cipher Block Chaining (PCBC) mode decryption

Figure 8.16: Propagating Cipher Block Chaining decryption (image is taken from Wikipedia article)

The good news is that we don’t really have to decrypt whole piece of data, but only slice by slice, this is exactly how I did in my previous example: 9.1.5 on page 915.

Now I’m trying all possible bytes (0..255) for each byte in key and just pick the byte producing maximal amount of 00/FF/8B bytes in a decrypted slice:

```python
#!/usr/bin/env python
import sys, hexdump, array, string, operator

KEY_LEN = 16

def chunks(l, n):
    # split n by l-byte chunks
    # https://stackoverflow.com/q/312443
    n = max(1, n)
    return [l[i:i + n] for i in range(0, len(l), n)]

def read_file(fname):
    file = open(fname, mode='rb')
    content = file.read()
    file.close()
    return content

def decrypt_byte(c, key):
    return chr((ord(c) - key) % 256)

def XOR_PCBC_step (IV, buf, k):
    prev = IV
```
rt=""
    for c in buf:
        new_c=decrypt_byte(c, k)
        plain=chr(ord(new_c)^ord(prev))
        prev=chr(ord(c)^ord(plain))
        rt=rt+plain
    return rt

each_Nth_byte=['' for c in buf]

content=read_file(sys.argv[1])
# split input by 16-byte chunks:
all_chunks=chunks(content, KEY_LEN)
for c in all_chunks:
    for i in range(KEY_LEN):
        each_Nth_byte[i]=each_Nth_byte[i] + c[i]

# try each byte of key
for N in range(KEY_LEN):
    print "N=", N
    stat={}
    for i in range(256):
        tmp_key=chr(i)
        tmp=XOR_PCBC_step(tmp_key,each_Nth_byte[N], N)
        # count 0, FFs and 8Bs in decrypted buffer:
        important_bytes=tmp.count('\x00')+tmp.count('\xFF')+tmp.count('\x8B')
        stat[i]=important_bytes
    sorted_stat = sorted(stat.items(), key=operator.itemgetter(1), reverse=True)
    print sorted_stat[0]

(Source code can be downloaded [here](#).)

I run it and here is a key for which 00/FF/8B bytes presence in decrypted buffer is maximal:

<table>
<thead>
<tr>
<th>N</th>
<th>count 0</th>
<th>count FF</th>
<th>count 8B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>147</td>
<td>1224</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>94</td>
<td>1327</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>252</td>
<td>1223</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>218</td>
<td>1266</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>38</td>
<td>1209</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>192</td>
<td>1378</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>199</td>
<td>1204</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>213</td>
<td>1332</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>225</td>
<td>1251</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>112</td>
<td>1223</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>143</td>
<td>1177</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>108</td>
<td>1286</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td>10</td>
<td>1164</td>
<td></td>
</tr>
<tr>
<td>13</td>
<td>3</td>
<td>1271</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td>128</td>
<td>1253</td>
<td></td>
</tr>
<tr>
<td>15</td>
<td>12</td>
<td>1330</td>
<td></td>
</tr>
</tbody>
</table>

Let's write decryption utility with the key we got:

```bash
#!/usr/bin/env python
```

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
import sys, hexdump, array

def xor_strings(s, t):
    # https://en.wikipedia.org/wiki/XOR_cipher#Example_implementation
    return "".join(chr(ord(a)^ord(b)) for a,b in zip(s, t))

def chunks(l, n):
    n = max(1, n)
    return [l[i:i+n] for i in range(0, len(l), n)]

def read_file(fname):
    file = open(fname, mode='rb')
    content = file.read()
    file.close()
    return content

def decrypt_byte(i, k):
    return chr((ord(i)-k) % 256)

def decrypt(buf):
    return "".join(decrypt_byte(buf[i], i) for i in range(16))

fout = open(sys.argv[2], mode='wb')

prev = IV
content = read_file(sys.argv[1])
tmp = chunks(content, 16)
for c in tmp:
    new_c = decrypt(c)
    p = xor_strings(new_c, prev)
    prev = xor_strings(c, p)
    fout.write(p)
fout.close()

(Source code can be downloaded here.)
Let's check resulting file:

$ objdump -b binary -m i386 -D decrypted.bin
...
 5:  8b ff    mov  %edi,%edi
 7:  55      push %ebp
 8:  8b ec    mov  %esp,%ebp
 a:  51      push %ecx
 b:  53      push %ebx
 c:  33 db    xor  %ebx,%ebx
 e:  43      inc  %ebx
 f:  84 1d a0 e2 05 01    test  %bl,0x105e2a0
15:  75 09    jne  0x20
17:  ff 75 08    pushl 0x8(%ebp)
1a:  ff 15 b0 13 00 01    call  *0x10013b0
20:  6a 6c    push $0x6c
22:  ff 35 54 d0 01 01    pushl 0x101d054
28:  ff 15 b4 13 00 01    call  *0x10013b4
2e:  89 45 fc    mov  %eax,-0x4(%ebp)
31:  85 c8    test  %eax,%eax

3a:  57      push %edi
3b:  6a 00    push $0x0
3d:  50      push %eax
3e:  ff 15 b8 13 00 01    call  *0x10013b8
44:  8b 35 bc 13 00 01    mov  0x10013bc,%esi
4a:  8b f8    mov  %eax,%edi

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Yes, this is seems correctly disassembled piece of x86 code. The whole decrypted file can be downloaded here.

In fact, this is text section from regedit.exe from Windows 7. But this example is based on a real case I encountered, so just executable is different (and key), algorithm is the same.

### 8.8.1 Other ideas to consider

What if I would fail with such simple frequency analysis? There are other ideas on how to measure correctness of decrypted/decompressed x86 code:

- Many modern compilers aligns functions on 0x10 border. So the space left before is filled with NOPs (0x90) or other NOP instructions with known opcodes: .1.7 on page 1011.

- Perhaps, the most frequent pattern in any assembly language is function call: `PUSH chain / CALL / ADD ESP, X`. This sequence can easily detected and found. I’ve even gathered statistics about average number of function arguments: 11.2 on page 972. (Hence, this is average length of PUSH chain.)

Read more about incorrectly/correctly disassembled code: 5.11 on page 726.

### 8.9 SAP

#### 8.9.1 About SAP client network traffic compression

(Tracing the connection between the TDW_NOCOMPRESS SAPGUI environment variable and the pesky annoying pop-up window and the actual data compression routine.)

It is known that the network traffic between SAPGUI and SAP is not encrypted by default, but compressed (see here and here).

It is also known that by setting the environment variable `TDW_NOCOMPRESS` to 1, it is possible to turn the network packet compression off.

But you will see an annoying pop-up window that cannot be closed:

---

25SAP GUI client

26http://go.yurichev.com/17221

27blog.yurichev.com

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's see if we can remove the window somehow.

But before this, let's see what we already know.

First: we know that the environment variable TDW_NOCOMPRESS is checked somewhere inside the SAPGUI client.

Second: a string like “data compression switched off” must be present somewhere in it.

With the help of the FAR file manager we can found that both of these strings are stored in the SAPguilib.dll file.

So let's open SAPguilib.dll in IDA and search for the TDW_NOCOMPRESS string. Yes, it is present and there is only one reference to it.

We see the following fragment of code (all file offsets are valid for SAPGUI 720 win32, SAPguilib.dll file version 7200,1,0,9009):

```
.text:6440D518    lea    eax, [ebp+2108h+var_211C]
.text:6440D51E    push   eax   ; int
.text:6440D51F    push   offset aTdw_nocompress ; "TDW_NOCOMPRESS"
.text:6440D524    mov    byte ptr [edi+15h], 0
.text:6440D528    call   chk_env
.text:6440D52D    pop     ecx
.text:6440D52E    pop     ecx
.text:6440D52F    push   offset byte 64443AF8
.text:6440D534    lea    ecx, [ebp+2108h+var_211C]

; demangled name: int ATL::CStringT::Compare(char const *)const
.text:6440D537    call   ds:mfc90_1603
.text:6440D53D    test   eax, eax
.text:6440D53F    jz     short loc 6440D55A
.text:6440D541    lea    ecx, [ebp+2108h+var_211C]

; demangled name: const char* ATL::CSimpleStringT::operator PCXSTR
.text:6440D544    call   ds:mfc90_910
```

http://go.yurichev.com/17347

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
The string returned by `chk_env()` via its second argument is then handled by the MFC string functions and then `atoi()`\(^{29}\) is called. After that, the numerical value is stored in edi+15h.

Also take a look at the `chk_env()` function (we gave this name to it manually):

```asm
.text:64413F20 ; int cdecl chk_env(char *VarName, int)
.text:64413F20 chk_env proc near
.text:64413F20 DstSize = dword ptr -0Ch
.text:64413F20 var 8 = dword ptr -8
.text:64413F20 DstBuf = dword ptr -4
.text:64413F20 VarName = dword ptr 8
.text:64413F20 arg 4 = dword ptr 0Ch
.text:64413F20 push ebp
.text:64413F21 mov ebp, esp
.text:64413F23 sub esp, 0Ch
.text:64413F26 mov [ebp+DstSize], 0
.text:64413F2D mov [ebp+DstBuf], 0
.text:64413F34 push offset unk_6444C88C
.text:64413F39 mov ecx, [ebp+arg 4]

; (demangled name) ATL::CStringT::operator=(char const *)
.text:64413F3C call ds:mfc90_820
.text:64413F42 mov eax, [ebp+VarName]

```

\(^{29}\)Standard C library function that converts the digits in a string to a number

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Yes. The `getenv_s()` function is a Microsoft security-enhanced version of `getenv()`.

There are also some MFC string manipulations.

Lots of other environment variables are checked as well. Here is a list of all variables that are being checked and what SAPGUI would write to its trace log when logging is turned on:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DPTRACE</td>
<td>“GUI-OPTION: Trace set to %d”</td>
</tr>
<tr>
<td>TDW_HEXDUMP</td>
<td>“GUI-OPTION: Hexdump enabled”</td>
</tr>
<tr>
<td>TDW_WORKDIR</td>
<td>“GUI-OPTION: working directory %s”</td>
</tr>
<tr>
<td>TDW_SPLASHSREENOFF</td>
<td>“GUI-OPTION: Splash Screen Off”</td>
</tr>
<tr>
<td>TDW_REPLYTIMEOUT</td>
<td>“GUI-OPTION: reply timeout %d milliseconds”</td>
</tr>
<tr>
<td>TDW_PLAYBACKTIMEOUT</td>
<td>“GUI-OPTION: PlaybackTimeout set to %d milliseconds”</td>
</tr>
<tr>
<td>TDW_NOCOMPRESS</td>
<td>“GUI-OPTION: no compression read”</td>
</tr>
<tr>
<td>TDW_EXPERT</td>
<td>“GUI-OPTION: expert mode”</td>
</tr>
<tr>
<td>TDW_PLAYBACKPROGRESS</td>
<td>“GUI-OPTION: PlaybackProgress”</td>
</tr>
<tr>
<td>TDW_PLAYBACKNETTRAFFIC</td>
<td>“GUI-OPTION: PlaybackNetTraffic”</td>
</tr>
<tr>
<td>TDW_PLAYLOG</td>
<td>“GUI-OPTION: /PlayLog is YES, file %s”</td>
</tr>
<tr>
<td>TDW_PLAYTIME</td>
<td>“GUI-OPTION: /PlayTime set to %d milliseconds”</td>
</tr>
<tr>
<td>TDW_LOGFILE</td>
<td>“GUI-OPTION: TDW_LOGFILE %s”</td>
</tr>
<tr>
<td>TDW_WAN</td>
<td>“GUI-OPTION: WAN - low speed connection enabled”</td>
</tr>
<tr>
<td>TDW_FULLMENU</td>
<td>“GUI-OPTION: FullMenu enabled”</td>
</tr>
<tr>
<td>SAP_CP / SAP_CODEPAGE</td>
<td>“GUI-OPTION: SAP_CODEPAGE %d”</td>
</tr>
<tr>
<td>UPDOWNLOAD_CP</td>
<td>“GUI-OPTION: UPDOWNLOAD_CP %d”</td>
</tr>
<tr>
<td>SNC_PARTNERNAME</td>
<td>“GUI-OPTION: SNC name %s”</td>
</tr>
<tr>
<td>SNC_QOP</td>
<td>“GUI-OPTION: SNC_QOP %s”</td>
</tr>
<tr>
<td>SNC_LIB</td>
<td>“GUI-OPTION: SNC is set to: %s”</td>
</tr>
<tr>
<td>SAPGUI_INPLACE</td>
<td>“GUI-OPTION: environment variable SAPGUI_INPLACE is on”</td>
</tr>
</tbody>
</table>

The settings for each variable are written in the array via a pointer in the EDI register. EDI is set before the function call:

```assembly
.text:64406E9E     lea   edi, [ebp+2884h+var_2884]  ; options here like +0x15...
.text:64406E93     lea   ecx, [esi+24h]
.text:64406E06     call  load_command_line
.text:64406E0B     mov   edi, eax
.text:64406E0D     xor   ebx, ebx
.text:64406E1F     cmp   edi, ebx
.text:64406E11     jz    short loc_64406E42
.text:64406E13     push  edi
```

---

30 MSDN
31 Standard C library returning environment variable

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Now, can we find the data record mode switched on string?

Yes, and the only reference is in

CDwsGui::PrepareInfoWindow().

How do we get know the class/method names? There are a lot of special debugging calls that write to the log files, like:

It is very useful.

So let's see the contents of this pesky annoying pop-up window's function:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!

call ds:mfc90_3178
push eax ; cchText
lea ecx, [esi+2854h]
; demangled name: const char* ATL::CSimpleStringT::operator PCXSTR
call ds:mfc90_910
push eax ; lpchText
push [ebp+var_10] ; hdc

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
At the start of the function ECX has a pointer to the object (since it is a thiscall (\[ECX\]:)) in our case, the object obviously has class type of CDwsGui. Depending on the option turned

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
on in the object, a specific message part is to be concatenated with the resulting message.

If the value at address this+0x3D is not zero, the compression is off:

```plaintext
This+0x3D
```

It is interesting that finally the var_10 variable state defines whether the message is to be shown at all:

```plaintext
For maximum data security delete
```

Let's check our theory on practice.

JNZ at this line ...

```plaintext
JNZ at this line ...

...replace it with just JMP, and we get SAPGUI working without the pesky annoying pop-up window appearing!

Now let's dig deeper and find a connection between the 0x15 offset in the load_command_line() (we gave it this name) function and the this+0x3D variable in CDwsGui::PrepareInfoWindow. Are we sure the value is the same?

We are starting to search for all occurrences of the 0x15 value in code. For a small programs like SAPGUI, it sometimes works. Here is the first occurrence we've got:

```plaintext
sub_64404C19
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The function has been called from the function named CDwsGui::CopyOptions! And thanks again for debugging information.

But the real answer is in CDwsGui::Init():

Finally, we understand: the array filled in the load_command_line() function is actually placed in the CDwsGui class, but at address this+0x28. 0x15 + 0x28 is exactly 0x3D. OK, we found the point where the value is copied to.

Let's also find the rest of the places where the 0x3D offset is used. Here is one of them in the CDwsGui::SapguiRun function (again, thanks to the debugging calls):

Let's check our findings.

Replace the setz al here with the xor eax, eax / nop instructions, clear the TDW_NOCOMPRESS environment variable and run SAPGUI. Wow! There pesky annoying window is no more (just as expected, because the variable is not set) but in Wireshark we can see that the network packets are not compressed.
At this point we know the compression flag is stored in the \texttt{CConnectionContext} object.

So, the compression flag is passed in the 5th argument of \texttt{CConnectionContext::CreateNetwork}. Inside the function, another one is called:

\texttt{...}
\texttt{.text:64403476 push [ebp+compression]}
\texttt{.text:64403479 push [ebp+arg_C]}
\texttt{.text:6440347C push [ebp+arg_8]}
\texttt{.text:6440347F push [ebp+arg_4]}
\texttt{.text:64403482 push [ebp+arg_0]}
\texttt{.text:64403485 call CNetwork\_CNetwork}

The compression flag is passed here in the 5th argument to the \texttt{CNetwork::CNetwork} constructor.

And here is how the \texttt{CNetwork} constructor sets the flag in the \texttt{CNetwork} object according to its 5th argument \textit{and} another variable which probably could also affect network packets compression.

\texttt{...}
\texttt{.text:64411DF1 cmp [ebp+compression], esi}
\texttt{.text:64411DF7 jz short set\_EAX\_to\_0}
\texttt{.text:64411DF9 mov al, [ebx+78h] ; another value may affect compression?}
\texttt{.text:64411DFC cmp al, '3'}
\texttt{.text:64411DFE jz short set\_EAX\_to\_1}
\texttt{.text:64411E00 cmp al, '4'}
\texttt{.text:64411E02 jnz short set\_EAX\_to\_0}
\texttt{.text:64411E04 set\_EAX\_to\_1:}
\texttt{.text:64411E04 xor eax, eax}
\texttt{.text:64411E06 inc eax ; EAX -> 1}
\texttt{.text:64411E07 jmp short loc\_64411E0B}
\texttt{.text:64411E09 set\_EAX\_to\_0:}
\texttt{.text:64411E09 xor eax, eax ; EAX -> 0}
\texttt{.text:64411E0B loc\_64411E0B:}
\texttt{.text:64411E0B mov [ebx+3A4h], eax ; EBX is pointer to CNetwork object}

At this point we know the compression flag is stored in the \texttt{CNetwork} class at address this+0x3A4.

Now let's dig through SAPguilib.dll for the 0x3A4 value. And here is the second occurrence in \texttt{CDwsGui::OnClientMessageWrite} (endless thanks for the debugging information):

\texttt{...}
\texttt{.text:64406F76 loc\_64406F76:}
\texttt{.text:64406F76 mov ecx, [ebp+7728h+var\_7794]}
\texttt{.text:64406F79 cmp dword ptr [ecx+3A4h], 1}
\texttt{.text:64406F80 jnz compression\_flag\_is\_zero}
\texttt{.text:64406F86 mov byte ptr [ebx+7], 1}
\texttt{.text:64406F8A mov eax, [esi+10h]}
\texttt{.text:64406F8D mov ecx, eax}
\texttt{.text:64406F8F test eax, eax}
\texttt{.text:64406F91 ja short loc\_64406FFF}
\texttt{.text:64406F93 mov ecx, [esi+14h]}
\texttt{.text:64406F96 mov eax, [esi+20h]}
\texttt{.text:64406F99 loc\_64406F99:}
\texttt{.text:64406F99 push dword ptr [edi+2868h] ; int}
\texttt{.text:64406F9F lea edx, [ebp+7728h+var\_77A4]}
\texttt{.text:64406FA2 push edx ; int}
\texttt{.text:64406FA3 push 30000 ; int}
\texttt{.text:64406FA8 lea edx, [ebp+7728h+Dst]}
\texttt{.text:64406FAB push edx ; Dst}
\texttt{.text:64406FAC push ecx ; int}
\texttt{.text:64406FAD push eax ; Src}
\texttt{.text:64406FAE push dword ptr [edi+28C0h] ; int}
\texttt{.text:64406FB4 call sub\_644055C5 ; actual compression routine}
\texttt{.text:64406FB9 add esp, 1Ch}
\texttt{.text:64406FBC cmp eax, 0FFFFF6Fh}
\texttt{.text:64406FBF jz short loc\_64407004}
\texttt{.text:64406FC1 cmp eax, 1}

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's take a look in sub_644055C5. In it we can only see the call to memcpy() and another function named (by IDA) sub_64417440.

And, let's take a look inside sub_64417440. What we see is:

Let's take a look in sub_644055C5. In it we can only see the call to memcpy() and another function named (by IDA) sub_64417440.

And, let's take a look inside sub_64417440. What we see is:

Voilà! We've found the function that actually compresses the data. As it was shown in past 32, this function is used in SAP and also the open-source MaxDB project. So it is available in source form.

Doing the last check here:

Voilà! We've found the function that actually compresses the data. As it was shown in past 32, this function is used in SAP and also the open-source MaxDB project. So it is available in source form.

Doing the last check here:

Replace JNZ here for an unconditional JMP. Remove the environment variable TDW_NOCOMPRESS. Voilà!

In Wireshark we see that the client messages are not compressed. The server responses, however, are compressed.

So we found exact connection between the environment variable and the point where data compression routine can be called or bypassed.

### 8.9.2 SAP 6.0 password checking functions

One time when the author of this book have returned again to his SAP 6.0 IDES installed in a VMware box, he figured out that he forgot the password for the SAP* account, then he have recalled it, but then he got this error message «Password logon no longer possible - too many failed attempts», since he’ve made all these attempts in attempt to recall it.

The first extremely good news was that the full disp+work.pdb PDB file is supplied with SAP, and it contain almost everything: function names, structures, types, local variable and argument names, etc. What a lavish gift!

There is TYPEINFODUMP utility for converting PDB files into something readable and grepable.

Here is an example of a function information + its arguments + its local variables:

| FUNCTION ThVmcSysEvent
| Address: 10143190 Size: 675 bytes Index: 60483 TypeIndex: 60484
| Type: int NEAR_C ThVmcSysEvent (unsigned int, unsigned char, unsigned short*)
| Flags: 0
| PARAMETER events
| Address: Reg335+288 Size: 4 bytes Index: 60488 TypeIndex: 60489
| Type: unsigned int
| Flags: d0
| PARAMETER opcode
| Address: Reg335+296 Size: 1 bytes Index: 60490 TypeIndex: 60491
| Type: unsigned char
| Flags: d0
| PARAMETER serverName
| Address: Reg335+304 Size: 8 bytes Index: 60492 TypeIndex: 60493
| Type: unsigned short*
| Flags: d0

http://go.yurichev.com/17312
http://go.yurichev.com/17038

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
And here is an example of some structure:

```
STRUCT DBSL_STMTID
Size: 120 Variables: 4 Functions: 0 Base classes: 0
MEMBER moduletype
  Type: DBSL_MODULETYPE
  Offset: 0 Index: 3 TypeIndex: 38653
MEMBER module
  Type: wchar_t module[40]
  Offset: 4 Index: 3 TypeIndex: 831
MEMBER stmtnum
  Type: long
  Offset: 84 Index: 3 TypeIndex: 440
MEMBER timestamp
  Type: wchar_t timestamp[15]
  Offset: 88 Index: 3 TypeIndex: 6612
```

Wow!

Another good news: debugging calls (there are plenty of them) are very useful.

Here you can also notice the `ct_level` global variable, that reflects the current trace level.

There are a lot of debugging inserts in the `disp+work.exe` file:

```
cmp   cs:ct_level, 1
jl    short loc_1400375DA
call  DpLock
lea   rcx, aDpxxtool4_c ;"dpxxtool4.c"
mov   edx, 4Eh ; line
call  CTrcSaveLocation
mov   r8, cs:func_48
mov   rcx, cs:hdl ; hdl
lea   rdx, aSDpreadmemvalu ; "%s: DpReadMemValue (%d)"
mov   r9d, ebx
call  DpTrcErr
call  DpUnlock
```

If the current trace level is bigger or equal to threshold defined in the code here, a debugging message is to be written to the log files like `dev_w0`, `dev_disp`, and other `dev*` files.

Let's try grepping in the file that we have got with the help of the TYPEINFODUMP utility:

```
cat "disp+work.pdb.d" | grep FUNCTION | grep -i password
```

We have got:

```
FUNCTION rcui::AgiPassword::DiagISelection
FUNCTION ssf_password_encrypt
FUNCTION ssf_password_decrypt
FUNCTION password_logon_disabled
FUNCTION dySignSkipUserPassword
```

34More about trace level: [http://go.yurichev.com/17039](http://go.yurichev.com/17039)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's also try to search for debug messages which contain the words «password» and «locked». One of them is the string «user was locked by subsequently failed password logon attempts», referenced in function password_attempt_limit_exceeded().

Other strings that this function can write to a log file are: «password logon attempt will be rejected immediately (preventing dictionary attacks)», «failed-logon lock: expired (but not removed due to ‘read-only’ operation)», «failed-logon lock: expired => removed».

After playing for a little with this function, we noticed that the problem is exactly in it. It is called from the chckpass() function — one of the password checking functions.

First, we would like to make sure that we are at the correct point:

Run tracer:

```
tracer64.exe -a:disp+work.exe bpf=disp+work.exe!chckpass,args:3,unicode
```

```
PID=2236|TID=2248| (0) disp+work.exe!chckpass (0x202c770, L"Brewered1 ⤽", 0x41) (called from 0x1402f1060 (disp+work.exe!usrexist+0x3c0))
```

The call path is: syssigni() -> DylSigni() -> dychksur() -> usrexist() -> chckpass().

The number 0x35 is an error returned in chckpass() at that point:

```
.text:00000001402ED567 loc_1402ED567: ; CODE XREF: chckpass+B4
.text:00000001402ED567 mov rcx, rbx ; usr02
.text:00000001402ED567A call password_idle_check
.text:00000001402ED567B cmp eax, 33h
.text:00000001402ED567C jz loc_1402EDB4E
.text:00000001402ED567D cmp eax, 36h
.text:00000001402ED567E jz loc_1402EDB3D
.text:00000001402ED567F xor edx, edx ; usr02_readonly
.text:00000001402ED5680 mov rcx, rbx ; usr02
.text:00000001402ED5681 call password_attempt_limit_exceeded
.text:00000001402ED5682 test al, al
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Fine, let's check:

```
tracer64.exe -a:disp+work.exe bpf=disp+work.exe!password_attempt_limit_exceeded,args:4,unicode, rt:0
```

PID=2744|TID=360|0 disp+work.exe!password_attempt_limit_exceeded (0x202c770, 0, 0x257758, 0) (called from 0x1402ed58b (disp+work.exe!chckpass+0xeb))
PID=2744|TID=360|0 disp+work.exe!password_attempt_limit_exceeded -> 1
PID=2744|TID=360|0 disp+work.exe!password_attempt_limit_exceeded (0x202c770, 0, 0, 0) (called from 0x1402e9794 (disp+work.exe!chngpass+0xe4))
PID=2744|TID=360|0 disp+work.exe!password_attempt_limit_exceeded -> 1
PID=2744|TID=360|0 We modify return value (EAX/RAX) of this function to 0

Excellent! We can successfully login now.

By the way, we can pretend we forgot the password, fixing the `chckpass()` function to return a value of 0 is enough to bypass the check:

```
tracer64.exe -a:disp+work.exe bpf=disp+work.exe!chckpass,args:3,unicode,rt:0
```

PID=2744|TID=360|0 disp+work.exe!chckpass (0x202c770, L"bogus", 0x41) (called from 0x1402f1060 (disp+work.exe!usrexist+0x3c0))
PID=2744|TID=360|0 disp+work.exe!chckpass -> 0x35
PID=2744|TID=360|0 We modify return value (EAX/RAX) of this function to 0

What also can be said while analyzing the `password_attempt_limit_exceeded()` function is that at the very beginning of it, this call can be seen:

```
lea  rcx, aLoginFailed_us : "login/failed_user_auto_unlock"
call sapgparam
```

test rax, rax
jz short loc_1402E19DE
movzx eax, word ptr [rax]
cmp ax, 'N'
jz short loc_1402E19D4
cmp ax, 'n'
jz short loc_1402E19D4
cmp ax, '0'
jnz short loc_1402E19DE

Obviously, function `sapgparam()` is used to query the value of some configuration parameter. This function can be called from 1768 different places. It seems that with the help of this information, we can easily find the places in code, the control flow of which can be affected by specific configuration parameters.

It is really sweet. The function names are very clear, much clearer than in the Oracle RDBMS.

It seems that the `disp+work` process is written in C++. Has it been rewritten some time ago?

### 8.10 Oracle RDBMS

#### 8.10.1 V$VERSION table in the Oracle RDBMS

Oracle RDBMS 11.2 is a huge program, its main module `oracle.exe` contain approx. 124,000 functions.

For comparison, the Windows 7 x86 kernel (`ntoskrnl.exe`) contains approx. 11,000 functions and the Linux 3.9.8 kernel (with default drivers compiled)—31,000 functions.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's start with an easy question. Where does Oracle RDBMS get all this information, when we execute this simple statement in SQL*Plus:

```sql
SQL> select * from V$VERSION;
```

And we get:

```text
BANNER
--------------------------------------------------------
Oracle Database 11g Enterprise Edition Release 11.2.0.1.0 - Production
PL/SQL Release 11.2.0.1.0 - Production
CORE 11.2.0.1.0 Production
TNS for 32-bit Windows: Version 11.2.0.1.0 - Production
NLSRTL Version 11.2.0.1.0 - Production
```

Let's start. Where in the Oracle RDBMS can we find the string `V$VERSION`?

In the win32-version, `oracle.exe` file contains the string, it's easy to see. But we can also use the object (.o) files from the Linux version of Oracle RDBMS since, unlike the win32 version `oracle.exe`, the function names (and global variables as well) are preserved there.

So, the `kqf.o` file contains the `V$VERSION` string. The object file is in the main Oracle-library `libserver11.a`. A reference to this text string can find in the `kqfviw` table stored in the same file, `kqf.o`:

```
Listing 8.8: kqf.o
```

```
.rodata:0800C4A0 kqfviw dd 08h ; DATA XREF: kqfchk:loc_8003A6D
.rodata:0800C4A0 ; kqfgbn+34

.rodata:0800C540 dd 3
.rodata:0800C544 dd 0
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
By the way, often, while analyzing Oracle RDBMS’s internals, you may ask yourself, why are the names of the functions and global variable so weird.

Probably, because Oracle RDBMS is a very old product and was developed in C in the 1980s.

And that was a time when the C standard guaranteed that the function names/variables can support only up to 6 characters inclusive: «6 significant initial characters in an external identifier»

Probably, the table kqfviw contains most (maybe even all) views prefixed with V$, these are fixed views, present all the time. Superficially, by noticing the cyclic recurrence of data, we can easily see that each kqfviw table element has 12 32-bit fields. It is very simple to create a 12-elements structure in IDA and apply it to all table elements. As of Oracle RDBMS version 11.2, there are 1023 table elements, i.e., in it are described 1023 of all possible fixed views.

We are going to return to this number later.

As we can see, there is not much information in these numbers in the fields. The first number is always equals to the name of the view (without the terminating zero). This is correct for each element. But this information is not very useful.

We also know that the information about all fixed views can be retrieved from a fixed view named V$FIXED_VIEW_DEFINITION (by the way, the information for this view is also taken from the kqfviw and kqfvip tables.) By the way, there are 1023 elements in those too. Coincidence? No.

```sql
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='V$VERSION';
VIEW_NAME -----------------------------
VIEW_DEFINITION -----------------------------
V$VERSION
select BANNER from GV$VERSION where inst_id = USERENV('Instance')
```

So, V$VERSION is some kind of a thunk view for another view, named GV$VERSION, which is, in turn:

```sql
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='GV$VERSION';
VIEW_NAME -----------------------------
VIEW_DEFINITION -----------------------------
GV$VERSION
select inst_id, banner from x$version
```

The tables prefixed with X$ in the Oracle RDBMS are service tables too, undocumented, cannot be changed by the user and are refreshed dynamically.

If we search for the text

```sql
select BANNER from GV$VERSION where inst_id = USERENV('Instance')
```

... in the kqf.o file, we find it in the kqfvip table:

```
Listing 8.9: kqf.o
.rodata:0800185A0 kqfvip dd offset _2__STRING_11126_0 ; DATA XREF: kqfgvcn+18
.rodata:0800185A0 ; kqfgvt+F
.rodata:0800185A0 ; "select inst_id,decode(indx,1,'data bloc"
.rodata:0800185A4 dd offset kqf459_c_0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The table appears to have 4 fields in each element. By the way, there are 1023 elements in it, again, the number we already know.

The second field points to another table that contains the table fields for this fixed view. As for V$VERSION, this table has only two elements, the first is 6 and the second is the BANNER string (the number 6 is this string’s length) and after, a terminating element that contains 0 and a null C string:

```
Listing 8.10: kqf.o
```

```
.rodata:080185A8  dd 0
.rodata:080185AC  dd 0
...
.rodata:08019570  dd offset _2 STRING_11378_0 ;
"select  BANNER from GV$VERSION where in"
.rodata:08019574  dd offset kqfv133_c_0
.rodata:08019578  dd 0
.rodata:0801957C  dd 0
.rodata:08019580  dd offset _2 STRING_11379_0 ;
"select inst_id,decode(bitand(cfflg,1),0"
.rodata:08019584  dd offset kqfv403_c_0
.rodata:08019588  dd 0
.rodata:0801958C  dd 0
.rodata:08019590  dd offset _2 STRING_11380_0 ;
"select  STATUS , NAME, IS_RECOVERY_DEST"
.rodata:08019594  dd offset kqfv199_c_0
```

By joining data from both kqfviw and kqfvip tables, we can get the SQL statements which are executed when the user wants to query information from a specific fixed view.

So we can write an oracle tables program, to gather all this information from Oracle RDBMS for Linux’s object files. For V$VERSION, we find this:

```
Listing 8.11: Result of oracle tables
```

```
kqfviw_element.viewname: [V$VERSION] ?: 0x3 0x43 0x1 0xffffc085 0x4
kqfvip_element.statement: [select BANNER from GV$VERSION where inst_id = USERENV('Instance')] 
kqfvip_element.params: [BANNER]
```

And:

```
Listing 8.12: Result of oracle tables
```

```
kqfviw_element.viewname: [GV$VERSION] ?: 0x3 0x26 0x2 0xffffc192 0x1
kqfvip_element.statement: [select inst_id, banner from x$version] 
kqfvip_element.params: [INST_ID] [BANNER]
```

The GV$VERSION fixed view is different from V$VERSION only in that it has one more field with the identifier instance.

Anyway, we are going to stick with the X$VERSION table. Just like any other X$-table, it is undocumented, however, we can query it:

```
SQL> select * from x$version;
ADDR  INDX  INST_ID
------- -------- -------
BANNER

0DBAF574 0 1
Oracle Database 11g Enterprise Edition Release 11.2.0.1.0 - Production
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This table has some additional fields, like ADDR and INDX.

While scrolling kqf.o in IDA we can spot another table that contains a pointer to the X$VERSION string, this is kqftab:

Listing 8.13: kqf.o

```c
.rodata:0803CAC0 dd 9 ; element number 0x1f6
.rodata:0803CAC4 dd offset _2__STRING_13113_0 ; "X$VERSION"
.rodata:0803CAC8 dd 4
.rodata:0803CACC dd offset _2__STRING_13114_0 ; "kqvt"
.rodata:0803CAD0 dd 4
.rodata:0803CAD4 dd 4
.rodata:0803CAD8 dd 0
.rodata:0803CADC dd 4
.rodata:0803CAE0 dd 0Ch
.rodata:0803CAE4 dd 0FFFFC075h
.rodata:0803CAE8 dd 3
.rodata:0803CAEC dd 0
.rodata:0803CAE0 dd 4
.rodata:0803CAE4 dd offset _2__STRING_13111_0 ; "X$KQFSZ"
.rodata:0803CAE8 dd 5
.rodata:0803CAE4 dd offset _2__STRING_13112_0 ; "kqfsz"
.rodata:0803CB00 dd 1
.rodata:0803CB04 dd 38h
.rodata:0803CB08 dd 0
.rodata:0803CB10 dd 1
.rodata:0803CB14 dd 0FFFFC09Dh
.rodata:0803CB18 dd 2
.rodata:0803CB1C dd 0
```

There are a lot of references to the X$-table names, apparently, to all Oracle RDBMS 11.2 X$-tables. But again, we don’t have enough information.

It’s not clear what does the kqvt string stands for.

The kq prefix may mean kernel or query.

v apparently stands for version and t—type? Hard to say.

A table with a similar name can be found in kqf.o:

Listing 8.14: kqf.o

```c
.rodata:0808C360 kqvt_c_0 kqftap_param <4, offset _2__STRING_19_0, 917h, 0, 0, 0, 4, 0, 0>
.rodata:0808C360 ; DATA XREF: .rodata:08042680
.rodata:0808C360 ; "ADDR"
.rodata:0808C360 ; "INDX"
.rodata:0808C360 ; "INST ID"
.rodata:0808C360 ; "BANNER"
.rodata:0808C360 kqftap_param <4, offset _2__STRING_20_0, 0802h, 0, 0, 0, 4, 0, 0> ;
.rodata:0808C3A8 kqftap_param <7, offset _2__STRING_21_0, 0802h, 0, 0, 0, 4, 0, 0> ;
.rodata:0808C3CC kqftap_param <6, offset _2__STRING_5017_0, 601h, 0, 0, 0, 50h, 0, 0> ;
.rodata:0808C3F0 kqftap_param <0, offset _2__STRING_0_0, 0, 0, 0, 0, 0, 0, 0, 0>
```

It contains information about all fields in the X$VERSION table. The only reference to this table is in the kqftap table:

Listing 8.15: kqf.o

```c
.rodata:08042680 kqftap_element <0, offset kqvt_c_0, offset kqvrow, 0> ;
```

It is interesting that this element here is 0x1f6th (502nd), just like the pointer to the X$VERSION string in the kqftab table.

Probably, the kqftap and kqftab tables complement each other, just like kqfvip and kqfviw.

We also see a pointer to the kqvrow() function. Finally, we got something useful!

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
So we will add these tables to our oracle tables utility too. For $X$VERSION we get:

Listing 8.16: Result of oracle tables

```plaintext
kqftab_element.name: [X$VERSION] ?: [kqvt] 0x4 0x4 0x4 0xc 0xffffc075 0x3
kqftap_param.name=[ADDR] ?: 0x917 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INDEX] ?: 0xb02 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INST_ID] ?: 0xb02 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[BANNER] ?: 0x601 0x0 0x0 0x0 0x50 0x0 0x0
kqftap_element.fn1=kqvrow
kqftap_element.fn2=NULL
```

With the help of tracer, it is easy to check that this function is called 6 times in row (from the qerfxFetch() function) while querying the $X$VERSION table.

Let's run tracer in cc mode (it comments each executed instruction):

```
tracer -a:oracle.exe bpf=oracle.exe!_kqvrow,trace:cc
```

```
_locqrow_ proc near

mov edi, [ebp+var_4] ; [EBP-4]=0xc98c938
mov eax, ebx
push EDX=0xcdefe554

Now it is easy to see that the row number is passed from outside. The function returns the string, constructing it as follows:

<table>
<thead>
<tr>
<th>String 1</th>
<th>Using vsnstr, vsnnum, vsnban global variables.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Calls sprintf().</td>
</tr>
<tr>
<td>String 2</td>
<td>Calls kkvsn().</td>
</tr>
<tr>
<td>String 3</td>
<td>Calls lmxver().</td>
</tr>
<tr>
<td>String 4</td>
<td>Calls npinli(), nrtnsvrs().</td>
</tr>
<tr>
<td>String 5</td>
<td>Calls lxvers().</td>
</tr>
</tbody>
</table>

That’s how the corresponding functions are called for determining each module’s version.

### 8.10.2 X$KSMLRU table in Oracle RDBMS

There is a mention of a special table in the *Diagnosing and Resolving Error ORA-04031 on the Shared Pool or Other Memory Pools [Video] [ID 146599.1]* note:

There is a fixed table called X$KSMLRU that tracks allocations in the shared pool that cause other objects in the shared pool to be aged out. This fixed table can be used to identify what is causing the large allocation.

If many objects are being periodically flushed from the shared pool then this will cause response time problems and will likely cause library cache latch contention problems when the objects are reloaded into the shared pool.

One unusual thing about the X$KSMLRU fixed table is that the contents of the fixed table are erased whenever someone selects from the fixed table. This is done since the fixed table stores only the largest allocations that have occurred. The values are reset after being selected so that subsequent large allocations can be noted even if they were not quite as large as others that occurred previously. Because of this resetting, the output of selecting from this table should be carefully kept since it cannot be retrieved back after the query is issued.

However, as it can be easily checked, the contents of this table are cleared each time it’s queried. Are we able to find why? Let’s get back to tables we already know: kqftab and kqftap which were generated with oracle tables’s help, that has all information about the X$-tables. We can see here that the ksmlrs() function is called to prepare this table’s elements:

```
Listing 8.17: Result of oracle tables

kqftab_element.name: [X$KSMLRU] ?: [ksmlr] 0x4 0x64 0x11 0xc 0xffffc0bb 0x5
kqftap_param.name=[ADDR] ?: 0x917 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INDEX] ?: 0xb02 0x0 0x0 0x0 0x0 0x0 0x0
kqftap_param.name=[INST_ID] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[KSMLRIDX] ?: 0xb02 0x0 0x0 0x4 0x0 0x0
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Indeed, with tracer's help it is easy to see that this function is called each time we query the X$KSMLRU table.

Here we see a reference to the ksmsplu_sp() and ksmsplu_jp() functions, each of them calls the ksmsplu() at the end. At the end of the ksmsplu() function we see a call to memset():

Listing 8.18: ksm.o

```assembly
.text:00434C50 loc_434C50: ; DATA XREF: .rdata:off_5E50EA8
.text:00434C50 mov edx, [ebp-4]
.text:00434C53 mov [eax], esi
.text:00434C55 mov esi, [edi]
.text:00434C57 mov [eax+4], esi
.text:00434C5A mov [edi], eax
.text:00434C5C add edx, 1
.text:00434C5F mov [ebp-4], edx
.text:00434C62 jnz loc_434B7D
.text:00434C68 mov ecx, [ebp+14h]
.text:00434C6B mov ebx, [ebp-10h]
.text:00434C6E mov esi, [ebp-0Ch]
.text:00434C71 mov edi, [ebp-8]
.text:00434C74 lea eax, [ecx+8Ch]
.text:00434C7A push 370h ; Size
.text:00434C7F push 0 ; Val
.text:00434C81 push eax ; Dst
.text:00434C82 call _intel_fast_memset
.text:00434C87 add esp, 0Ch
.text:00434C8A mov esp, ebp
.text:00434C8C pop ebp
.text:00434C8D retn
.text:00434C8D _ksmsplu endp
```

Constructions like memset (block, 0, size) are often used just to zero memory block. What if we take a risk, block the memset() call and see what happens?

Let's run tracer with the following options: set breakpoint at 0x434C7A (the point where the arguments to memset() are to be passed), so that tracer will set program counter EIP to the point where the arguments passed to memset() are to be cleared (at 0x434C8A) It can be said that we just simulate an unconditional jump from address 0x434C7A to 0x434C8A.

```
tracer -a:oracle.exe bpx=oracle.exe!0x00434C7A,set(eip,0x00434C8A)
```

(Important: all these addresses are valid only for the win32 version of Oracle RDBMS 11.2)

Indeed, now we can query the X$KSMLRUI table as many times as we want and it is not being cleared anymore!

Just in case, do not try this on your production servers.

It is probably not a very useful or desired system behavior, but as an experiment for locating a piece of code that we need, it perfectly suits our needs!
8.10.3 V$TIMER table in Oracle RDBMS

V$TIMER is another fixed view that reflects a rapidly changing value:

V$TIMER displays the elapsed time in hundredths of a second. Time is measured since the beginning of the epoch, which is operating system specific, and wraps around to 0 again whenever the value overflows four bytes (roughly 497 days).

(From Oracle RDBMS documentation 39)

It is interesting that the periods are different for Oracle for win32 and for Linux. Will we be able to find the function that generates this value?

As we can see, this information is finally taken from the X$KSUTM table.

SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='V$TIMER';

<table>
<thead>
<tr>
<th>VIEW_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>VIEW_DEFINITION</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>V$TIMER</td>
</tr>
<tr>
<td>select HSECS from GV$TIMER where inst_id = USERENV('Instance')</td>
</tr>
</tbody>
</table>

SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='GV$TIMER';

<table>
<thead>
<tr>
<th>VIEW_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>VIEW_DEFINITION</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>GV$TIMER</td>
</tr>
<tr>
<td>select inst_id,ksutmtim from x$ksutm</td>
</tr>
</tbody>
</table>

Now we are stuck in a small problem, there are no references to value generating function(s) in the tables kqftab/kqftap:

Listing 8.19: Result of oracle tables

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>[ksutm] 0x1 0x4 0x4 0x0 0xfffffc09b 0x3</td>
<td>[ADDR] 0x10917 0x0 0x0 0x4 0x0 0x0</td>
<td>[INDX] 0x20b02 0x0 0x0 0x4 0x0 0x0</td>
<td>[INST_ID] 0xb02 0x0 0x0 0x4 0x0 0x0</td>
<td>[KSUTMTIM] 0x1302 0x0 0x0 0x4 0x0 0xe</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

When we try to find the string KSUTMTIM, we see it in this function:

```
kqfd_DRN_ksutm_c proc near        ; DATA XREF: .rodata:0805B4E8
    arg_0 = dword ptr 8
    arg_8 = dword ptr 10h
    arg_C = dword ptr 14h
    push    ebp
    mov     ebp, esp
    push    [ebp+arg_C]
    push    offset ksutm
    push    offset _2__STRING_1263_0 ; "KSUTMTIM"
    push    [ebp+arg_8]
    push    [ebp+arg_0]
    call    kqfd_cfui_drain
    add     esp, 14h
    mov     esp, ebp
    pop     ebp
    retn
```

39http://go.yurichev.com/17088

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The `kqfd_DRN_ksutm_c()` function is mentioned in the `kqfd_tab_registry_0` table:

```
dd offset .2_STRING_62_0 ; "X$KSUTM"
dd offset kqfd_OPN_ksutm_c
dd offset kqfd_tabl_fetch
dd 0
dd 0
dd offset kqfd_DRN_ksutm_c
```

There is a function `ksugtm()` referenced here. Let's see what's in it (Linux x86):

```
Listing 8.20: ksu.o
ksugtm proc near

var_1C = byte ptr -1Ch
arg_4 = dword ptr 0Ch

push ebp
mov ebp, esp
sub esp, 1Ch
lea eax, [ebp+var_1C]
push eax
call slgcs
pop ecx
mov edx, [ebp+arg_4]
mov [edx], eax
mov eax, 4
mov esp, ebp
pop ebp
retn

ksugtm endp
```

The code in the win32 version is almost the same. Is this the function we are looking for? Let's see:

```
tracer -a:oracle.exe bpf=oracle.exe!_ksugtm,args:2,dump_args:0x4
```

Let's try again:

```
SQL> select * from V$TIMER;

            HSECS
----------
  27294929

SQL> select * from V$TIMER;

            HSECS
----------
  27295006

SQL> select * from V$TIMER;

            HSECS
----------
  27295167
```

Listing 8.21: tracer output

```
TID=2428(0) oracle.exe!_ksugtm (0x0, 0xd76c5f0) (called from oracle.exe!__VInfreq_qerfxFetch/\+0xfd (0x56bb6d5))
Argument 2/2
0D76C5F0: 38 C9 "8."
TID=2428(0) oracle.exe!_ksugtm () -> 0x4 (0x4)
Argument 2/2 difference
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Indeed—the value is the same we see in SQL*Plus and it is returned via the second argument.

Let's see what is in slgcs() (Linux x86):

```assembly
slgcs proc near

var_4 = dword ptr -4
arg_0 = dword ptr 8

push ebp
mov ebp, esp
push esi
mov [ebp+var_4], ebx
mov eax, [ebp+arg_0]
call $+5
pop ebx
nop ; PIC mode
mov ebx, offset _GLOBAL_OFFSET_TABLE_
mov dword ptr [eax], 0
mov sltrgatime64 ; PIC mode
push 0
push 0Ah
push edx
push eax
call __udivdi3 ; PIC mode
mov ebx, [ebp+var_4]
add esp, 10h
mov esp, ebp
pop ebp
retn

slgcs endp
```

(it is just a call to sltrgatime64())

and division of its result by 10 (3.10 on page 504)

And win32-version:

```assembly
_slgcs proc near ; CODE XREF: dbg elfElResetCount+15
    ;_dbgerRunActions+1528
db 66h
nop
push ebp
mov ebp, esp
mov eax, [ebp+8]
mov dword ptr [eax], 0
call ds:__imp__GetTickCount@0 ; GetTickCount()
mov edx, eax
mov eax, 0CCCCCDDh
mul edx
shr edx, 3
mov eax, edx
mov esp, ebp
pop ebp
retn
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
It is just the result of `GetTickCount()` \(^{40}\) divided by 10 (\(3.10\) on page \(504\)).

Voilà! That's why the win32 version and the Linux x86 version show different results, because they are generated by different OS functions.

*Drain* apparently implies *connecting* a specific table column to a specific function.

We will add support of the table `kqfd_tabl_registry_0` to oracle tables\(^ {41}\), now we can see how the table column's variables are *connected* to a specific functions:

```plaintext
[XKSUTM] [kqfd_OPN_ksutm_c] [kqfd_tabl_fetch] [NULL] [NULL] [kqfd_DRN_ksutm_c]
[XKSUSGIF] [kqfd_OPN_ksusg_c] [kqfd_tabl_fetch] [NULL] [NULL] [kqfd_DRN_ksusg_c]
```

*OPN*, apparently stands for, *open*, and *DRN*, apparently, for *drain*.

## 8.11 Handwritten assembly code

### 8.11.1 EICAR test file

This .COM-file is intended for testing antivirus software, it is possible to run in in MS-DOS and it prints this string: “EICAR-STANDARD-ANTIVIRUS-TEST-FILE!” \(^ {42}\).

Its important property is that it consists entirely of printable ASCII-symbols, which, in turn, makes it possible to create it in any text editor:

```plaintext
X5O!P%@AP[4\PZX54(P^)7CC)7}$EICAR-STANDARD-ANTIVIRUS-TEST-FILE!$H+H*
```

Let's decompile it:

```assembly
; initial conditions: SP=0FFFEh, SS:[SP]=0
0100 58 pop ax
0101 35 4F 21 xor ax, 214Fh
0104 50 push ax
0105 25 40 41 and ax, 4140h
0108 50 push ax
0109 5B pop bx
010A 34 5C xor al, 5Ch
010C 50 push ax
010D 5A pop dx
010E 58 pop ax
010F 35 34 28 xor ax, 2834h
0112 50 push ax
0113 5E pop si
0114 29 37 sub [bx], si
0116 43 inc bx
0117 43 inc bx
0118 29 37 sub [bx], si
011A 7D 24 jge short near ptr word_10140
011C 45 49 43 ... db 'EICAR-STANDARD-ANTIVIRUS-TEST-FILE!$'
0140 48 2B word_10140 dw 2B48h ; CD 21 (INT 21) will be here
0142 48 2A dw 2A48h ; CD 20 (INT 20) will be here
```

\(^ {40}\)MSDN
\(^ {41}\)yurichev.com
\(^ {42}\)wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We will add comments about the registers and stack after each instruction.

Essentially, all these instructions are here only to execute this code:

<table>
<thead>
<tr>
<th>Address</th>
<th>mnemonic</th>
<th>opcodes</th>
<th>op</th>
<th>function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0144 0D</td>
<td>db</td>
<td>00</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0145 0A</td>
<td>db</td>
<td>09</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0146 09</td>
<td>MOV</td>
<td>AH, 9</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0147 1C</td>
<td>MOV</td>
<td>DX, 11C</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0148 01</td>
<td>MOV</td>
<td>DX, 11C</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0149 CD</td>
<td>INT</td>
<td>21h</td>
<td></td>
<td></td>
</tr>
<tr>
<td>014A CD</td>
<td>INT</td>
<td>20h</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

INT 21h with 9th function (passed in AH) just prints a string, the address of which is passed in DS:DX. By the way, the string has to be terminated with the ‘$’ sign. Apparently, it’s inherited from CP/M and this function was left in DOS for compatibility. INT 20h exits to DOS.

But as we can see, these instruction’s opcodes are not strictly printable. So the main part of EICAR file is:

- preparing the register (AH and DX) values that we need;
- preparing INT 21 and INT 20 opcodes in memory;
- executing INT 21 and INT 20.

By the way, this technique is widely used in shellcode construction, when one have to pass x86 code in string form.

Here is also a list of all x86 instructions which have printable opcodes: .1.6 on page 1010.

### 8.12 Demos

Demos (or demomaking) were an excellent exercise in mathematics, computer graphics programming and very tight x86 hand coding.

#### 8.12.1 10 PRINT CHR$(205.5+RND(1));: GOTO 10

All examples here are MS-DOS .COM files.

In [Nick Montfort et al, 10 PRINT CHR$(205.5+RND(1));: GOTO 10, (The MIT Press:2012)](http://go.yurichev.com/17286) we can read about one of the most simple possible random maze generators.

It just prints a slash or backslash characters randomly and endlessly, resulting in something like this:

There are a few known implementations for 16-bit x86.

43Also available as [http://go.yurichev.com/17286](http://go.yurichev.com/17286)
The listing was taken from his website[^1], but the comments are mine.

```
00000000: B9D007    mov    cx,007D0 ; limit output to 2000 characters
00000003: 31C0    xor    ax,ax    ; command to timer chip
00000005: E643    out    043,al    ; read 8-bit of timer
00000009: D1E8    shr    ax,1    ; get second bit to CF flag
0000000B: D1E8    shr    ax,1
0000000D: B05C    mov    al,05C  ; if CF=1, skip the next instruction
00000012: 7202    jc     00000022    ; if CF=0, reload AL register with another character
00000017: B02F    mov    al,02F  ;/'
00000019: B40E    mov    ah,00E
00000024: CD10    int    010
00000026: E2E1    loop    00000009    ; loop 2000 times
00000028: CD20    int    020    ; exit to DOS
```

The pseudo-random value here is in fact the time that has passed from the system’s boot, taken from the 8253 time chip, the value increases by one 18.2 times per second.

By writing zero to port 43h, we send the command “select counter 0”, “counter latch”, “binary counter” (not a BCD value).

The interrupts are enabled back with the POPF instruction, which restores the IF flag as well.

It is not possible to use the IN instruction with registers other than AL, hence the shuffling.

**My attempt to reduce Trixter’s version: 27 bytes**

We can say that since we use the timer not to get a precise time value, but a pseudo-random one, we do not need to spend time (and code) to disable the interrupts.

Another thing we can say is that we need only one bit from the low 8-bit part, so let’s read only it.

We can reduced the code slightly and we’ve got 27 bytes:

```
00000000: B9D007    mov    cx,007D0 ; limit output to 2000 characters
00000003: 31C0    xor    ax,ax    ; command to timer chip
00000005: E643    out    043,al    ; read 8-bit of timer
00000009: D1E8    shr    ax,1    ; get second bit to CF flag
0000000B: D1E8    shr    ax,1
0000000D: B05C    mov    al,05C  ; prepare ‘\'
0000000F: 7202    jc     00000013
00000011: B02F    mov    al,02F  ;/'
00000013: B40E    mov    ah,00E
00000015: CD10    int    010
00000017: E2E1    loop    00000003    ; exit to DOS
```

[^1]: [http://go.yurichev.com/17305](http://go.yurichev.com/17305)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Taking random memory garbage as a source of randomness

Since it is MS-DOS, there is no memory protection at all, we can read from whatever address we want. Even more than that: a simple LODSB instruction reads a byte from the DS:SI address, but it’s not a problem if the registers’ values are not set up, let it read 1) random bytes; 2) from a random place in memory!

It is suggested in Trixter’s webpage\(^45\) to use LODSB without any setup.

It is also suggested that the SCASB instruction can be used instead, because it sets a flag according to the byte it reads.

Another idea to minimize the code is to use the INT 29h DOS syscall, which just prints the character stored in the AL register.

That is what Peter Ferrie did\(^46\):

```
Listing 8.22: Peter Ferrie: 10 bytes

; AL is random at this point
00000000: AE scasb
; CF is set according subtracting random memory byte from AL.
; so it is somewhat random at this point
00000001: D6 setalc
; AL is set to 0xFF if CF=1 or to 0 if otherwise
00000002: 242D and al, 02D ;'.'
; AL here is 0x2D or 0
00000004: 042F add al, 02F ;'/'
; AL here is 0x5C or 0x2F
00000006: CD29 int 029 ; output AL to screen
00000008: EBF6 jmps
```

So it is possible to get rid of conditional jumps at all. The ASCII code of backslash ("\") is 0x5C and 0x2F for slash ("/"). So we have to convert one (pseudo-random) bit in the CF flag to a value of 0x5C or 0x2F.

This is done easily: by AND-ing all bits in AL (where all 8 bits are set or cleared) with 0x2D we have just 0 or 0x2D.

By adding 0x2F to this value, we get 0x5D or 0x2F.

Then we just output it to the screen.

**Conclusion**

It is also worth mentioning that the result may be different in DOSBox, Windows NT and even MS-DOS, due to different conditions: the timer chip can be emulated differently and the initial register contents may be different as well.

---

Mandelbrot set is a fractal, which exhibits self-similarity. When you increase scale, you see that this characteristic pattern repeating infinitely.

Here is a demo written by “Sir_Lagsalot” in 2009, that draws the Mandelbrot set, which is just a x86 program with executable file size of only 64 bytes. There are only 30 16-bit x86 instructions.

Here it is what it draws:

Let’s try to understand how it works.

**Theory**

**A word about complex numbers**

A complex number is a number that consists of two parts—real (Re) and imaginary (Im).

The complex plane is a two-dimensional plane where any complex number can be placed: the real part is one coordinate and the imaginary part is the other.

Some basic rules we have to keep in mind:

- **Addition**: $(a + bi) + (c + di) = (a + c) + (b + d)i$
- In other words:

---

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
\[
\text{Re}(\text{sum}) = \text{Re}(a) + \text{Re}(b) \\
\text{Im}(\text{sum}) = \text{Im}(a) + \text{Im}(b)
\]

- **Multiplication:** \((a + bi)(c + di) = (ac - bd) + (bc + ad)i\)

  In other words:
  \[
  \text{Re}(\text{product}) = \text{Re}(a) \cdot \text{Re}(c) - \text{Re}(b) \cdot \text{Re}(d) \\
  \text{Im}(\text{product}) = \text{Im}(b) \cdot \text{Im}(c) + \text{Im}(a) \cdot \text{Im}(d)
  \]

- **Square:** \((a + bi)^2 = (a + bi)(a + bi) = (a^2 - b^2) + (2ab)i\)

  In other words:
  \[
  \text{Re}(\text{square}) = \text{Re}(a)^2 - \text{Im}(a)^2 \\
  \text{Im}(\text{square}) = 2 \cdot \text{Re}(a) \cdot \text{Im}(a)
  \]

### How to draw the Mandelbrot set

The Mandelbrot set is a set of points for which the \(z_{n+1} = z_n^2 + c\) recursive sequence (where \(z\) and \(c\) are complex numbers and \(c\) is the starting value) does not approach infinity.

In plain English language:

- Enumerate all points on screen.
- Check if the specific point is in the Mandelbrot set.
- Here is how to check it:
  - Represent the point as a complex number.
  - Calculate the square of it.
  - Add the starting value of the point to it.
  - Does it go off limits? If yes, break.
  - Move the point to the new place at the coordinates we just calculated.
  - Repeat all this for some reasonable number of iterations.
- The point is still in limits? Then draw the point.
- The point has eventually gone off limits?
  - (For a black-white image) do not draw anything.
  - (For a colored image) transform the number of iterations to some color. So the color shows the speed with which point has gone off limits.

Here is Pythonesque algorithm for both complex and integer number representations:

#### Listing 8.23: For complex numbers

```
def check_if_is_in_set(P):
    P_start=P
    iterations=0

    while True:
        if (P>bounds):
            break
        P=P^2+P_start
        if iterations > max_iterations:
            break
        iterations++

    return iterations
```

# black-white

for each point on screen P:
    if check_if_is_in_set (P) < max_iterations:
        draw point

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The integer version is where the operations on complex numbers are replaced with integer operations according to the rules which were explained above.

Listing 8.24: For integer numbers

```python
def check_if_is_in_set(X, Y):
    X_start=X
    Y_start=Y
    iterations=0

    while True:
        if (X^2 + Y^2 > bounds):
            break
        new_X=X^2 - Y^2 + X_start
        new_Y=2*X*Y + Y_start
        if iterations > max_iterations:
            break
        iterations++

    return iterations
```

# black-white
for X = min_X to max_X:
    for Y = min_Y to max_Y:
        if check_if_is_in_set (X,Y) < max_iterations:
            draw point at X, Y

# colored
for X = min_X to max_X:
    for Y = min_Y to max_Y:
        iterations = if check_if_is_in_set (X,Y)
        map iterations to color
        draw color point at X,Y

Here is also a C# source which is present in the Wikipedia article, but we’ll modify it so it will print the iteration numbers instead of some symbol:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace Mnoj
{
    class Program
    {
        static void Main(string[] args)
        {
            double realCoord, imagCoord;
            double realTemp, imagTemp, realTemp2, arg;
            int iterations;

            for (imagCoord = 1.2; imagCoord >= -1.2; imagCoord -= 0.05)
            {
                for (realCoord = -0.6; realCoord <= 1.77; realCoord += 0.03)
                {
                    iterations = 0;
                    realTemp = realCoord;
                    imagTemp = imagCoord;
                    arg = (realCoord * realCoord) + (imagCoord * imagCoord);
                    while ((arg < 2*2) && (iterations < 40))
                    {
```

[48]wikipedia
[49] HERE is also the executable file: beginners.re

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
realTemp2 = (realTemp * realTemp) - (imagTemp * imagTemp) - realCoord;
imagTemp = (2 * realTemp * imagTemp) - imagCoord;
realTemp = realTemp2;
arg = (realTemp * realTemp) + (imagTemp * imagTemp);
iterations += 1;
} Console.Write("\{0,2:D\} \n, iterations);
} Console.Write("\n");
} Console.ReadKey();
}

Here is the resulting file, which is too wide to be included here:
beginners.re.

The maximal number of iterations is 40, so when you see 40 in this dump, it means that this point has been wandering for 40 iterations but never got off limits.

A number $n$ less than 40 means that point remained inside the bounds only for $n$ iterations, then it went outside them.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There is a cool demo available at http://go.yurichev.com/17309, which shows visually how the point moves on the plane at each iteration for some specific point. Here are two screenshots.

First, we've clicked inside the yellow area and saw that the trajectory (green line) eventually swirls at some point inside:

Figure 8.18: Click inside yellow area

This implies that the point we've clicked belongs to the Mandelbrot set.
Then we've clicked outside the yellow area and saw a much more chaotic point movement, which quickly went off bounds:

![Figure 8.19: Click outside yellow area](image)

This means the point doesn't belong to Mandelbrot set.

Another good demo is available here: [http://go.yurichev.com/17310](http://go.yurichev.com/17310).

(For statistics collecting purposes) if you've read this far, please click [here](http://go.yurichev.com/17310). Thanks!
Let’s get back to the demo

The demo, although very tiny (just 64 bytes or 30 instructions), implements the common algorithm described here, but using some coding tricks.

The source code is easily downloadable, so here is it, but let’s also add comments:

```
Listing 8.25: Commented source code

; X is column on screen
; Y is row on screen

; X=0, Y=0 X=319, Y=0

; +--------------------->
; |
; |
; |
; |
; |
; |
; v
; X=0, Y=199 X=319, Y=199

; switch to VGA 320*200*256 graphics mode
mov al,13h
int 10h
; initial BX is 0
; initial DI is 0xFFFF
; DS:BX (or DS:0) is pointing to Program Segment Prefix at this moment
; ... first 4 bytes of which are CD 20 FF 9F
les ax,[bx]
; ES:AX=9FFF:20CD

FillLoop:
; set DX to 0. CWD works as: DX:AX = sign_extend(AX).
; AX here 0x20CD (at startup) or less than 320 (when getting back after loop),
; so DX will always be 0.
cwd
mov ax,di
; AX is current pointer within VGA buffer
; divide current pointer by 320
mov cx,320
div cx
; DX (start_X) - remainder (column: 0..319); AX - result (row: 0..199)
sub ax,100
; AX=AX-100, so AX (start_Y) now is in range -100..99
; DX is in range 0..319 or 0x0000..0x013F
dec dh
; DX now is in range 0xFF00..0x003F (-256..63)
xor bx,bx
xor si,si
; BX (temp_X)=0; SI (temp_Y)=0
; get maximal number of iterations
; CX is still 320 here, so this is also maximal number of iteration
MandalLoop:
mov bp,si
imul si,bx
; SI = temp_X*temp_Y
add si,si
; SI = SI*2 = (temp_X*temp_Y)*2
imul bx,bx
; BX = BX^2 = temp_X^2
jo MandelBreak ; overflow?
imul bp,bp
; BP = BP^2 = temp_Y^2
jo MandelBreak ; overflow?
add bx,bp
; BX = BX+BP = temp_X^2 + temp_Y^2
jo MandelBreak ; overflow?
sub bx,bp
; BX = BX-BP = temp_X^2 - temp_Y^2
sub bx,bp
; BX = BX-BP = temp_X^2 - temp_Y^2

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
```
Algorithm:

- Switch to 320*200 VGA video mode, 256 colors. $320 \times 200 = 64000$ (0xFA00).
  
  Each pixel is encoded by one byte, so the buffer size is 0xFA00 bytes. It is addressed using the ES:DI registers pair.

  ES must be 0xA000 here, because this is the segment address of the VGA video buffer, but storing 0xA000 to ES requires at least 4 bytes (PUSH 0A000h / POP ES). You can read more about the 16-bit MS-DOS memory model here: 11.6 on page 976.

  Assuming that BX is zero here, and the Program Segment Prefix is at the zeroth address, the 2-byte LES AX,[BX] instruction stores 0x20CD to AX and 0x9FFF to ES.

  So the program starts to draw 16 pixels (or bytes) before the actual video buffer. But this is MS-DOS, there is no memory protection, so a write happens into the very end of conventional memory, and usually, there is nothing important. That’s why you see a red strip 16 pixels wide at the right side. The whole picture is shifted left by 16 pixels. This is the price of saving 2 bytes.

- An infinite loop processes each pixel. Probably, the most common way to enumerate all pixels on the screen is with two loops: one for the X coordinate, another for the Y coordinate. But then you’ll need to multiply the coordinates to address a byte in the VGA video buffer.

  The author of this demo decided to do it otherwise: enumerate all bytes in the video buffer by using one single loop instead of two, and get the coordinates of the current point using division. The resulting coordinates are: X in the range of $-256::63$ and Y in the range of $-100::99$. You can see on the screenshot that the picture is somewhat shifted to the right part of screen.

  That’s because the biggest heart-shaped black hole usually appears on coordinates 0,0 and these are shifted here to right. Could the author just subtract 160 from the value to get X in the range of $-160::159$? Yes, but the instruction SUB DX, 160 takes 4 bytes, while DEC DH—2 bytes (which subtracts 0x100 (256) from DX). So the whole picture is shifted for the cost of another 2 bytes of saved space.

  - Check, if the current point is inside the Mandelbrot set. The algorithm is the one that has been described here.

  - The loop is organized using the L00P instruction, which uses the CX register as counter.

    The author could set the number of iterations to some specific number, but he didn’t: 320 is already present in CX (has been set at line 35), and this is good maximal iteration number anyway. We save here some space by not the reloading CX register with another value.

    - IMUL is used here instead of MUL, because we work with signed values: keep in mind that the 0,0 coordinates has to be somewhere near the center of the screen.

      It’s the same with SAR (arithmetic shift for signed values): it’s used instead of SHR.

    - Another idea is to simplify the bounds check. We must check a coordinate pair, i.e., two variables. What the author does is to checks thrice for overflow: two squaring operations and one addition.

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
Indeed, we use 16-bit registers, which hold signed values in the range of -32768..32767, so if any of the coordinates is greater than 32767 during the signed multiplication, this point is definitely out of bounds: we jump to the MandelBreak label.

- There is also a division by 64 (SAR instruction). 64 sets scale.

Try to increase the value and you can get a closer look, or to decrease if for a more distant look.

• We are at the MandelBreak label, there are two ways of getting here: the loop ended with CX=0 (the point is inside the Mandelbrot set); or because an overflow has happened (CX still holds some value). Now we write the low 8-bit part of CX (CL) to the video buffer.

The default palette is rough, nevertheless, 0 is black: hence we see black holes in the places where the points are in the Mandelbrot set. The palette can be initialized at the program’s start, but keep in mind, this is only a 64 bytes program!

• The program runs in an infinite loop, because an additional check where to stop, or any user interface will result in additional instructions.

Some other optimization tricks:

• The 1-byte CWD is used here for clearing DX instead of the 2-byte XOR DX, DX or even the 3-byte Mov DX, 0.

• The 1-byte XCHG AX, CX is used instead of the 2-byte MOV AX,CX. The current value of AX is not needed here anyway.

• DI (position in video buffer) is not initialized, and it is 0xFFFF at the start 50.

That’s OK, because the program works for all DI in the range of 0..0xFFFF eternally, and the user can’t notice that it is started off the screen (the last pixel of a 320*200 video buffer is at address 0xF9FF). So some work is actually done off the limits of the screen.

Otherwise, you’ll need an additional instructions to set DI to 0 and check for the video buffer’s end.

My “fixed” version

Listing 8.26: My “fixed” version

```
1  org 100h
2  mov al,13h
3  int 10h
4
5  ; set palette
6  mov dx, 3c8h
7  mov al, 0
8  out dx, al
9  mov cx, 100h
10  inc dx
11  l00:
12  mov al, cl
13  shl ax, 2
14  out dx, al ; red
15  out dx, al ; green
16  out dx, al ; blue
17  loop l00
18
19  push 0a000h
20  pop es
21
22  xor di, di
23
24  FillLoop:
25  cwd
26  mov ax,di
27  mov cx,320
28  div cx
29  sub ax,100
30  sub dx,160
31  50 More information about initial register values: http://go.yurichev.com/17004

```
xor bx, bx
xor si, si

MandelLoop:
mov bp, si
imul si, bx
add si, si
imul bx, bx
jo MandelBreak
imul bp, bp
jo MandelBreak
add bx, bp
jo MandelBreak
sub bx, bp
sub bx, bp
sar bx, 6
add bx, dx
sar si, 6
add si, ax
loop MandelLoop

MandelBreak:
xchg ax, cx
stosb
cmp di, 0FA00h
jb FillLoop

; wait for keypress
xor ax, ax
int 16h
; set text video mode
mov ax, 3
int 10h
; exit
int 20h

The author of these lines made an attempt to fix all these oddities: now the palette is smooth grayscale, the video buffer is at the correct place (lines 19..20), the picture is drawn on center of the screen (line 30), the program eventually ends and waits for the user’s keypress (lines 58..68).

But now it’s much bigger: 105 bytes (or 54 instructions) \(^{51}\).

\(^{51}\) You can experiment by yourself: get DosBox and NASM and compile it as: nasm file.asm -fbin -o file.com

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!

8.13 Other examples

An example about Z3 and manual decompilation was here. It is moved there: https://yurichev.com/writings/SAT_SMT_by_example.pdf.
Chapter 9

Examples of reversing proprietary file formats

9.1 Primitive XOR-encryption

9.1.1 Simplest ever XOR encryption

I once saw a software where all debugging messages has been encrypted using XOR by value of 3. In other words, two lowest bits of all characters has been flipped.

“Hello, world” would become “Kfool/#tlqog”:

```python
#!/usr/bin/python
msg = "Hello, world!"
print "".join(map(lambda x: chr(ord(x)^3), msg))
```

This is quite interesting encryption (or rather obfuscation), because it has two important properties: 1) single function for encryption/decryption, just apply it again; 2) resulting characters are also printable, so the whole string can be used in source code without escaping characters.

The second property exploits the fact that all printable characters organized in rows: 0x2x-0x7x, and when you flip two lowest bits, character moving 1 or 3 characters left or right, but never moved to another (maybe non-printable) row:

![Figure 9.1: 7-bit ASCII table in Emacs](image)

...with a single exception of 0x7F character.

For example, let’s encrypt characters in A-Z range:

```python
#!/usr/bin/python
msg = "@ABCDEFGHIJKLMNO"
print "".join(map(lambda x: chr(ord(x)^3), msg))
```
Result:
CBA@GFEDKJIHONML

It’s like “@” and “C” characters have been swapped, and so are “B” and “a”.
Yet again, this is an interesting example of exploiting XOR properties, rather than encryption: the very same effect of *preserving printableness* can be achieved while flipping any of lowest 4 bits, in any combination.
9.1.2 Norton Guide: simplest possible 1-byte XOR encryption

Norton Guide\(^1\) was popular in the epoch of MS-DOS, it was a resident program that worked as a hypertext reference manual.

Norton Guide’s databases are files with the extension .ng, the contents of which look encrypted:

![Figure 9.2: Very typical look](image)

| 000000170: | 00 00 00 00 00 00 00 00 00 |

| 000000310: | 1A 63 19 72 3A 1A 1A 84 |
| 000000320: | 33 1A 1A A7 19 7F 37 1A |

Why did we think that it’s encrypted but not compressed?

We see that the 0x1A byte (looking like “→”) occurs often, it would not be possible in a compressed file.

We also see long parts that consist only of Latin letters, and they look like strings in an unknown language.

\(^1\)wikipedia

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Since the 0x1A byte occurs so often, we can try to decrypt the file, assuming that it’s encrypted by the simplest XOR-encryption.

If we apply XOR with the 0x1A constant to each byte in Hiew, we can see familiar English text strings:

![Figure 9.3: Hiew XORing with 0x1A](image)

XOR encryption with one single constant byte is the simplest possible encryption method, which is, nevertheless, encountered sometimes.

Now we understand why the 0x1A byte is occurring so often: because there are so many zero bytes and they were replaced by 0x1A in encrypted form.

But the constant might be different. In this case, we could try every constant in the 0..255 range and look for something familiar in the decrypted file. 256 is not so much.

**Entropy**

A very important property of such primitive encryption systems is that the information entropy of the encrypted/decrypted block is the same.

Here is my analysis in Wolfram Mathematica 10.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
What we do here is load the file, get its entropy, decrypt it, save it and get the entropy again (the same!). Mathematica also offers some well-known English language texts for analysis.

So we also get the entropy of Shakespeare’s sonnets, and it is close to the entropy of the file we just analyzed.

The file we analyzed consists of English language sentences, which are close to the language of Shakespeare.

And the XOR-ed bitwise English language text has the same entropy.

However, this is not true when the file is XOR-ed with a pattern larger than one byte.

The file we analyzed can be downloaded here: [http://go.yurichev.com/17350](http://go.yurichev.com/17350).

**One more word about base of entropy**

Wolfram Mathematica calculates entropy with base of $e$ (base of the natural logarithm), and the UNIX `ent` utility uses base 2.

So we set base 2 explicitly in `Entropy` command, so Mathematica will give us the same results as the `ent` utility.

---

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
9.1.3 Simplest possible 4-byte XOR encryption

If a longer pattern was used for XOR-encryption, for example a 4 byte pattern, it’s easy to spot as well. For example, here is the beginning of the kernel32.dll file (32-bit version from Windows Server 2008):

Figure 9.4: Original file

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here it is “encrypted” with a 4-byte key:

Figure 9.5: “Encrypted” file

It’s very easy to spot the recurring 4 symbols.
Indeed, the header of a PE-file has a lot of long zero areas, which are the reason for the key to become visible.
Here is the beginning of a PE-header in hexadecimal form:

![PE-header](image)

**Figure 9.6: PE-header**
Here it is “encrypted”:

![Image of the encrypted PE-header](image)

**Figure 9.7: “Encrypted” PE-header**

It’s easy to spot that the key is the following 4 bytes: 8C 61 D2 63.

With this information, it’s easy to decrypt the whole file.

So it is important to keep in mind these properties of PE-files: 1) PE-header has many zero-filled areas; 2) all PE-sections are padded with zeros at a page boundary (4096 bytes), so long zero areas are usually present after each section.

Some other file formats may contain long zero areas.

It’s typical for files used by scientific and engineering software.

For those who want to inspect these files on their own, they are downloadable here: [http://go.yurichev.com/17352](http://go.yurichev.com/17352).

**Exercise**

9.1.4 Simple encryption using XOR mask

I've found an old interactive fiction game while diving deep into *if-archive*:

The New Castle v3.5 - Text/Adventure Game in the style of the original Infocom (tm) type games, Zork, Collosal Cave (Adventure), etc. Can you solve the mystery of the abandoned castle?

There is a file inside (named castle.dbf) which is clearly encrypted, but not by a real crypto algorithm, nor it's compressed, this is something rather simpler. I wouldn't even measure entropy level (9.2 on page 920) of the file, because I'm sure it's low. Here is how it looks like in Midnight Commander:

Will it be possible to decrypt it without accessing to the program, using just this file?

There is a clearly visible pattern of repeating string. If a simple encryption by XOR mask was applied, such repeating strings is a prominent signature, because, probably, there were a long lacunas of zero bytes, which, in turn, are present in many executable files as well as in binary data files.

Here I'll dump the file's beginning using *xxd* UNIX utility:

```
... 

00000030: 09 61 0d 63 0f 77 14 69 75 62 67 76 01 7e 1d 61 .a.c.w.iubgv.~.a
00000040: 7a 11 0f 72 6e 03 05 7d 7d 63 7e 77 66 1e 7a 02 z..rn..}}c~wf.z.
00000050: 75 50 02 4a 31 71 31 33 5c 27 08 5c 51 74 3e 39 uP.J1q13\\'.
00000060: 50 2e 28 72 24 4b 38 21 4l 09 37 38 3b 51 41 2d P.(r$K8!L.78;QA-
00000070: 1c 3c 37 5d 27 5a 1c 7c 6a 10 14 68 77 08 6d 1a .<7}Z.|j..hw.m.
```

Figure 9.8: Encrypted file in Midnight Commander

Will it be possible to decrypt it without accessing to the program, using just this file?

There is a clearly visible pattern of repeating string. If a simple encryption by XOR mask was applied, such repeating strings is a prominent signature, because, probably, there were a long lacunas of zero bytes, which, in turn, are present in many executable files as well as in binary data files.

Here I’ll dump the file’s beginning using *xxd* UNIX utility:

```
... 

00000030: 09 61 0d 63 0f 77 14 69 75 62 67 76 01 7e 1d 61 .a.c.w.iubgv.~.a
00000040: 7a 11 0f 72 6e 03 05 7d 7d 63 7e 77 66 1e 7a 02 z..rn..}}c~wf.z.
00000050: 75 50 02 4a 31 71 31 33 5c 27 08 5c 51 74 3e 39 uP.J1q13\\'.
00000060: 50 2e 28 72 24 4b 38 21 4l 09 37 38 3b 51 41 2d P.(r$K8!L.78;QA-
00000070: 1c 3c 37 5d 27 5a 1c 7c 6a 10 14 68 77 08 6d 1a .<7}Z.|j..hw.m.
```

http://www.ifarchive.org/

As in https://en.wikipedia.org/wiki/Lacuna_(manuscripts)

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's stick at visible repeating iubgv string. By looking at this dump, we can clearly see that the period of the string occurrence is 0x51 or 81. Probably, 81 is size of block? The size of the file is 1658961, and it can be divided evenly by 81 (and there are 20481 blocks then).

Now I'll use Mathematica to analyze, are there repeating 81-byte blocks in the file? I'll split input file by 81-byte blocks and then I'll use `Tally` function which just counts, how many times some item has been occurred in the input list. Tally's output is not sorted, so I also add `Sort` function to sort it by number of occurrences in descending order.

input = BinaryReadList["/home/dennis/.../castle.dbf"];
blocks = Partition[input, 81];
stat = Sort[Tally[blocks], #1[[2]] > #2[[2]] &]

And here is output:

```

```

(For statistics collecting purposes) if you've read this far, please click [here](https://reference.wolfram.com/language/ref/Tally.html). Thanks!
Anyway, let's try to use the most occurred block as a XOR key and try to decrypt four first 81-byte blocks.

102, 30, 122, 2, 117, 125, 107, 25, 99, 109, 114, 100, 3, 5, 125, 125, 99, 126, 119, 102, 30, 122, 2, 117, 1

Let's compare first block (occurred 1739 times) and the second (occurred 1422 times):

\[
\text{In[] := BitXor[stat[[1]][[1]], stat[[2]][[1]]]}
\]

They are differ only in the second byte.

Let's compare the second block (occurred 1422 times) and the third (occurred 1012 times):

\[
\text{In[] := BitXor[stat[[2]][[1]], stat[[3]][[1]]]}
\]

They are also differ only in the second byte.

Anyway, let's try to use the most occurred block as a XOR key and try to decrypt four first 81-byte blocks in the file:

\[
\text{In[] := key = stat[[1]][[1]]}
\]

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Let's try to decrypt the whole file:

```
DecryptBlock[blk_] := BitXor[key, blk]
decrypted = Map[DecryptBlock[#] &, blocks];
BinaryWrite["/home/dennis/.../tmp", Flatten[decrypted]]
Close["/home/dennis/.../tmp"]
```

(I've replaced unprintable characters by “?”.)

So we see that the first and the third blocks are empty (or almost empty), but the second and the fourth has clearly visible English language words/phrases. It seems that our assumption about key is correct (at least partially). This means that the most occurred 81-byte block in the file can be found at places of lacunas of zero bytes or something like that.

Let's try to decrypt the whole file:

```
DecryptBlock[blk_] := BitXor[key, blk]
decrypted = Map[DecryptBlock[#] &, blocks];
BinaryWrite["/home/dennis/.../tmp", Flatten[decrypted]]
Close["/home/dennis/.../tmp"]
```
Figure 9.9: Decrypted file in Midnight Commander, 1st attempt

Looks like some kind of English phrases from some game, but something wrong. First of all, cases are inverted: phrases and some words are started with lowercase characters, while other characters are in upper case. Also, some phrases started with wrong letters. Take a look at the very first phrase: “eHE WEED OF CRIME BEARS BITTER FRUIT”. What is “eHE”? Isn’t “tHE” have to be here? Is it possible that our decryption key has wrong byte at this place?

Let’s look again at the second block in the file, at key and at decryption result:

```
In[:]= blocks[[2]]
Out[]= {80, 2, 74, 49, 113, 49, 51, 92, 39, 8, 92, 81, 116, 62,

```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Encrypted byte is 2, the byte from the key is 103, $2 \oplus 103 = 101$ and 101 is ASCII code for “e” character. What byte of a key must be equal to, so the resulting ASCII code will be 116 (for “t” character)? $2 \oplus 116 = 118$, let’s put 118 in key at the second byte ...

...and decrypt the whole file again.

Figure 9.10: Decrypted file in Midnight Commander, 2nd attempt

Wow, now the grammar is correct, all phrases started with correct letters. But still, case inversion is suspicious. Why would game’s developer write them in such a manner? Maybe our key is still incorrect? While observing ASCII table we can notice that uppercase and lowercase letter’s ASCII codes are differ in just one bit (6th bit starting at 1st, 0b100000):

6th bit set in a zero byte has decimal form of 32. But 32 is ASCII code for space!

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Indeed, one can switch case just by XOR-ing ASCII character code with 32 (more about it: 3.17.3 on page 544).

It is possible that the empty lacunas in the file are not zero bytes, but rather spaces? Let's modify XOR key one more time (I'll XOR each byte of key by 32):

(* "32" is scalar and "key" is vector, but that's OK *)

```
In[]:= key3 = BitXor[32, key]
Out[] = {112, 86, 34, 84, 81, 70, 86, 57, 67, 40, 51, 55, 84, 93, 75, 
57, 67, 77, 82, 70, 46, 89, 83, 63, 41, 85, 81, 79, 37, 36, 95, 60, 
90, 69, 40, 78, 46, 50, 92, 74, 48, 52, 72, 87, 40, 77, 58, 74, 41, 
65, 45, 67, 47, 87, 52, 73, 85, 66, 71, 86, 33, 94, 61, 65, 90, 49, 
47, 82, 78, 35, 37, 93, 93, 67, 94, 87, 70, 62, 90, 34, 85}
```

Let's decrypt the input file again:

```
/home/dennis/P/RE-book/decrypt_dat_file/tmp3
1

Figure 9.12: Decrypted file in Midnight Commander, final attempt

(Decrypted file is available here: https://github.com/DennisYurichev/RE-for-beginners/blob/master/ff/XOR/mask_1/files/decrypted.dat.bz2.)

This is undoubtedly a correct source file. Oh, and we see numbers at the start of each block. It has to be a source of our erroneous XOR key. As it seems, the most occurred 81-byte block in the file is a block filled with spaces and containing “1” character at the place of second byte. Indeed, somehow, many blocks here are interleaved with this one. Maybe it’s some kind of padding for short phrases/messages? Other frequently occurred 81-byte blocks are also space-filled blocks, but with different digit, hence, they are differ only at the second byte.

That’s all! Now we can write an utility to encrypt the file back, and maybe modify it before.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Summary: XOR encryption like that is not robust at all. It has been intended by game’s developer(s), probably, just to prevent gamer(s) to peek into internals of game, nothing else more serious. Still, encryption like that is extremely popular due to its simplicity and many reverse engineers are usually familiar with it.

9.1.5 Simple encryption using XOR mask, case II

I've got another encrypted file, which is clearly encrypted by something simple, like XOR-ing:

```
/home/dennis/tmp/cipher.txt  0x00000000
00000000 0F 01 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
00000000 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F 00 01 02 03 04
00000000 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F 00 01 02 03
00000000 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F 00 01 02
```

Figure 9.13: Encrypted file in Midnight Commander

The encrypted file can be downloaded here.

ent Linux utility reports about \( \sim 7.5 \) bits per byte, and this is high level of entropy (9.2 on page 920), close to compressed or properly encrypted file. But still, we clearly see some pattern, there are some blocks with size of 17 bytes, and you can see some kind of ladder, shifting by 1 byte at each 16-byte line.

It's also known that the plain text is just English language text.

Now let's assume that this piece of text is encrypted by simple XOR-ing with 17-byte key.

I tried to find some repeating 17-byte blocks using Mathematica, like I did before in my previous example (9.1.4 on page 908):

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
In[] := input = BinaryReadList["/home/dennis/tmp/cipher.txt"];
In[] := blocks = Partition[input, 17];
In[] := Sort[Tally[blocks], #1[[2]] > #2[[2]] &]

Out[] := {{
{248, 128, 88, 63, 58, 175, 159, 154, 232, 226, 161, 50, 97, 127, 3, 217, 80}, 1},
{252, 217, 1, 39, 39, 238, 143, 223, 241, 235, 170, 91, 75, 119, 2, 152, 82}, 1},
{244, 204, 88, 112, 59, 234, 151, 147, 165, 238, 170, 118, 49, 126, 27, 144, 82}, 1},
{241, 196, 78, 112, 54, 224, 142, 223, 242, 236, 186, 58, 37, 50, 17, 144, 95}, 1},
{176, 201, 71, 112, 56, 230, 143, 151, 234, 246, 187, 118, 44, 125, 8, 156, 17}, 1},
...
{249, 206, 71, 34, 42, 254, 142, 154, 235, 247, 239, 57, 34, 113, 27, 138, 88}, 1},
{157, 170, 84, 32, 32, 225, 199, 139, 237, 236, 188, 51, 97, 124, 21, 141, 17}, 1},
{248, 197, 1, 61, 32, 253, 149, 150, 235, 228, 188, 122, 97, 97, 27, 143, 84}, 1},
{252, 217, 1, 38, 42, 253, 130, 223, 233, 226, 187, 51, 97, 123, 20, 217, 69}, 1},
{245, 211, 13, 112, 56, 231, 148, 223, 242, 226, 188, 118, 52, 97, 15, 152, 93}, 1},
{221, 210, 15, 112, 28, 231, 158, 141, 233, 236, 172, 61, 97, 90, 21, 149, 92}, 1}}

No luck, each 17-byte block is unique within the file and occurred only once. Perhaps, there are no 17-byte zero lacunas, or lacunas containing only spaces. It is possible indeed: such long space indentation and padding may be absent in tightly typeset text.

The first idea is to try all possible 17-byte keys and find those, which will result in readable text after decryption. Bruteforce is not an option, because there are $2^{17}$ possible keys (~$10^{40}$), that's too much.

But there are good news: who said we have to test 17-byte key as a whole, why can't we test each byte of key separately? It is possible indeed.

Now the algorithm is:

- try all 256 bytes for 1st byte of key;
- decrypt 1st byte of each 17-byte blocks in the file;
- are all decrypted bytes we got are printable? keep tabs on it;
- do so for all 17 bytes of key.

I've written the following Python script to check this idea:

```
Listing 9.3: Python script

each_Nth_byte=['']*KEY_LEN

content=read_file(sys.argv[1])
# split input by 17-byte chunks:
all_chunks=chunks(content, KEY_LEN)
for c in all_chunks:
    for i in range(KEY_LEN):
        each_Nth_byte[i]=each_Nth_byte[i] + c[i]

# try each byte of key
for N in range(KEY_LEN):
    print "N=%", N
    possible_keys=[]
    for i in range(256):
        tmp_key=chr(i)*len(each_Nth_byte[N])
        tmp=xor_strings(tmp_key,each_Nth_byte[N])
        # are all characters in tmp[] are printable?
        if is_string_printable(tmp)==False:
            continue
        possible_keys.append(i)
    print possible_keys, "len=%", len(possible_keys)
```

(Full version of the source code is here.)

Here is its output:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
So there are 2 or 3 possible bytes for each byte of 17-byte key. This is much better than 256 possible bytes for each byte, but still too much. There are up to 1 million of possible keys:

Listing 9.4: Mathematica

\[
\text{In}[1] := 3 \times 2 \times 3 \times 2 \times 2 \times 3 \times 2 \times 3 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2
\]
\[
\text{Out}[1] = 995328
\]

It’s possible to check all of them, but then we must check visually, if the decrypted text is looks like English language text.

Let’s also take into consideration the fact that we deal with 1) natural language; 2) English language. Natural languages has some prominent statistical features. First of all, punctuation and word lengths. What is average word length in English language? Let’s just count spaces in some well-known English language texts using Mathematica.

Here is “The Complete Works of William Shakespeare” text file from Gutenberg Library:

Listing 9.5: Mathematica

\[
\text{In}[1] := \text{input} = \text{BinaryReadList}[/\text{home/dennis/tmp/pg100.txt}];
\]
\[
\text{In}[1] := \text{Tally}[\text{input}]
\]
\[
\text{Out}[1] = \{(239, 1), (187, 1), (191, 1), (84, 39878), (104, 218875), (101, 406157), (32, 1285884), (80, 12038), (114, 299907), (111, 282560), (106, 2788), (99, 67194), (116, 291243), (71, 11261), (117, 115225), (110, 216805), (98, 46768), (103, 57328), (69, 42703), (66, 15450), (107, 29345), (102, 69103), (67, 21526), (109, 95890), (112, 46849), (108, 146532), (87, 16508), (115, 215605), (105, 199130), (97, 245509), (83, 34802), (44, 83315), (121, 85549), (13, 124787), (10, 124787), (119, 73155), (100, 134216), (118, 34077), (46, 78216), (89, 9128), (45, 8150), (76, 29319), (42, 73), (79, 33268), (82, 29040), (73, 55893), (72, 18468), (68, 15726), (58, 1843), (65, 44560), (49, 982), (58, 373), (48, 325), (91, 2076), (35, 3), (93, 2068), (74, (For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There are 1285884 spaces in the whole file, and the frequency of space occurrence is 1 space per ~4.3 characters.

Now here is Alice’s Adventures in Wonderland, by Lewis Carroll from the same library:

The result is different probably because of different formatting of these texts (maybe indentation and/or padding).

OK, so let’s assume the average frequency of space in English language is 1 space per 4..7 characters.

Now the good news again: we can measure frequency of spaces while decrypting our file gradually. Now I count spaces in each slice and throw away 1-byte keys which produce results with too small number of spaces (or too large, but this is almost impossible given so short key):

The result is different probably because of different formatting of these texts (maybe indentation and/or padding).

OK, so let’s assume the average frequency of space in English language is 1 space per 4..7 characters.

Now the good news again: we can measure frequency of spaces while decrypting our file gradually. Now I count spaces in each slice and throw away 1-byte keys which produce results with too small number of spaces (or too large, but this is almost impossible given so short key):
# count spaces in decrypted buffer:
spaces=tmp.count(' ')
if spaces==0:
    continue
spaces_ratio=len(tmp)/spaces
if spaces_ratio<4:
    continue
if spaces_ratio>7:
    continue
possible_keys.append(i)

print possible_keys, "len=", len(possible_keys)

(Full version of the source code is here.)

This reports just one single possible byte for each byte of key:

N= 0
[144] len= 1
N= 1
[160] len= 1
N= 2
[33] len= 1
N= 3
[80] len= 1
N= 4
[79] len= 1
N= 5
[143] len= 1
N= 6
[251] len= 1
N= 7
[255] len= 1
N= 8
[133] len= 1
N= 9
[131] len= 1
N= 10
[207] len= 1
N= 11
[86] len= 1
N= 12
[65] len= 1
N= 13
[18] len= 1
N= 14
[122] len= 1
N= 15
[249] len= 1
N= 16
[49] len= 1

Let's check this key in Mathematica:

Listing 9.8: Mathematica

In[]:= input = BinaryReadList["/home/dennis/tmp/cipher.txt"];

In[]:= blocks = Partition[input, 17];

In[]:= key = {144, 160, 33, 80, 79, 143, 251, 255, 133, 131, 207, 86, 65, 18, 122, 249, 49};

In[]:= EncryptBlock[blk_] := BitXor[key, blk]

In[]:= encrypted = Map[EncryptBlock[#] &, blocks];

In[]:= BinaryWrite["/home/dennis/tmp/plain2.txt", Flatten[encrypted]]

In[]:= Close["/home/dennis/tmp/plain2.txt"]

And the plain text is:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Mr. Sherlock Holmes, who was usually very late in the mornings, save upon those not infrequent occasions when he was up all night, was seated at the breakfast table. I stood upon the hearth-rug and picked up the stick which our visitor had left behind him the night before. It was a fine, thick piece of wood, bulbous-headed, of the sort which is known as a "Penang lawyer." Just under the head was a broad silver band nearly an inch across. "To James Mortimer, M.R.C.S., from his friends of the C.C.H.," was engraved upon it, with the date "1884." It was just such a stick as the old-fashioned family practitioner used to carry--dignified, solid, and reassuring.

"Well, Watson, what do you make of it?"

Holmes was sitting with his back to me, and I had given him no sign of my occupation.

...
Texts written in natural languages are also can be compressed tightly, because natural languages has a lot of redundancy (otherwise, a tiny typo will always lead to misunderstanding, like any toggled bit in compressed archive make decompression nearly impossible), some words are used very often, etc. In everyday speech, it’s possible to drop up to half of words and it still be recognizable.

Code for CPUs is also can be compressed, because some ISA instructions are used much more often than others. In x86, most used instructions are MOV/PUSH/CALL (5.11.2 on page 731).

Data compressors and ciphers tend to produce very high entropy results. Good PRNG also produce data which cannot be compressed (it is possible to measure their quality by this sign).

So, in other words, entropy is a measure which can help to probe contents of unknown data block.

### 9.2.1 Analyzing entropy in Mathematica

(This part has been first appeared in my blog at 13-May-2015. Some discussion: https://news.ycombinator.com/item?id=9545276.)

It is possible to slice a file by blocks, calculate entropy of each and draw a graph. I did this in Wolfram Mathematica for demonstration and here is a source code (Mathematica 10):

```mathematica
(* loading the file *)
input=BinaryReadList["file.bin"];

(* setting block sizes *)
BlockSize=4096;BlockSizeToShow=256;

(* slice blocks by 4k *)
blocks=Partition[input,BlockSize];

(* how many blocks we've got? *)
Length[blocks]

(* calculate entropy for each block. 2 in Entropy[] (base) is set with the intention so Entropy[] function will produce the same results as Linux ent utility does *)
entropies=Map[N[Entropy[2,#]]&,blocks];

(* helper functions *)
fBlockToShow[input_,offset_]:=Take[input,{1+offset,1+offset+BlockSizeToShow}]
fToASCII[val_]:=FromCharacterCode[val,\"PrintableASCII\"]
fToHex[val_]:=IntegerString[val,16]
fPutASCIIWindow[data_]:=Framed[Grid[Partition[Map[fToASCII,data],16]]]
fPutHexWindow[data_]:=Framed[Grid[Partition[Map[fToHex,data],16],Alignment->Right]]

(* that will be the main knob here *)
{Slider[Dynamic[offset],{0,Length[input]-BlockSize,BlockSize}],Dynamic[BaseForm[offset,16]]}

(* main UI part *)
Dynamic[{ListLinePlot[entropies,GridLines->{{-1,offset/BlockSize,1}},Filling->Axis,AxesLabel->\"offset\",\"entropy\"]},
CurrentBlock=fBlockToShow[input,offset];
fPutHexWindow[CurrentBlock],
fPutASCIIWindow[CurrentBlock]]
```

**GeoIP ISP database**

Let’s start with the GeoIP file (which assigns ISP to the block of IP addresses). This binary file GeoIPISP.dat has some tables (which are IP address ranges perhaps) plus some text blob at the end of the file (containing ISP names).

When I load it to Mathematica, I see this:
There are two parts in graph: first is somewhat chaotic, second is more steady.

0 in horizontal axis in graph means lowest entropy (the data which can be compressed very tightly, ordered in other words) and 8 is highest (cannot be compressed at all, chaotic or random in other words). Why 0 and 8? 0 means 0 bits per byte (byte as a container is not filled at all) and 8 means 8 bits per byte, i.e., the whole byte container is filled with the information tightly.

So I put slider to point in the middle of the first block, and I clearly see some array of 32-bit integers. Now I put slider in the middle of the second block and I see English text:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Indeed, this are names of ISPs. So, entropy of English text is 4.5-5.5 bits per byte? Yes, something like this. Wolfram Mathematica has some well-known English literature corpus embedded, and we can see entropy of Shakespeare’s sonnets:

\[
\text{In[1]} := \text{Entropy[2, ExampleData[{"Text", "ShakespearesSonnets"}]]/N}
\]
\[
\text{Out[1]} = 4.42366
\]

4.4 is close to what we’ve got (4.7-5.3). Of course, classic English literature texts are somewhat different from ISP names and other English texts we can find in binary files (debugging/logging/error messages), but this value is close.

**TP-Link WR941 firmware**

Next example. I’ve got firmware for TP-Link WR941 router:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We see here 3 blocks with empty lacunas. Then the first block with high entropy (started at address 0) is small, second (address somewhere at 0x22000) is bigger and third (address 0x123000) is biggest. I can't be sure about exact entropy of the first block, but 2nd and 3rd has very high entropy, meaning that these blocks are either compressed and/or encrypted.

I tried `binwalk` for this firmware file:

<table>

<td>Falling entropy edge (0.732390)</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Rising edges are corresponding to rising edges of block on our graph. Falling edges are the points where empty lacunas are started.

Binwalk can also generate PNG graphs (-E -J):

What can we say about lacunas? By looking in hex editor, we see that these are just filled with 0xFF bytes. Why developers put them? Perhaps, because they weren’t able to calculate precise compressed blocks sizes, so they allocated space for them with some reserve.

**Notepad**

Another example is notepad.exe I’ve picked in Windows 8.1:
There is cavity at ≈ 0x19000 (absolute file offset). I've opened the executable file in hex editor and found imports table there (which has lower entropy than x86-64 code in the first half of graph).

There are also high entropy block started at ≈ 0x20000:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
In hex editor I can see PNG file here, embedded in the PE file resource section (it is a large image of notepad icon). PNG files are compressed, indeed.

Unnamed dashcam

Now the most advanced example in this part is the firmware of some unnamed dashcam I’ve received from a friend:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The cavity at the very beginning is an English text: debugging messages. I checked various ISAs and I found that the first third of the whole file (with the text segment inside) is in fact MIPS (little-endian) code. For instance, this is very distinctive MIPS function epilogue:

```
move $sp, $fp
lw $ra, 0x1C($sp)
lw $fp, 0x18($sp)
```

From our graph we can see that MIPS code has entropy of 5-6 bits per byte. Indeed, I once measured various ISAs entropy and I’ve got these values:

- x86: .text section of ntoskrnl.exe file from Windows 2003: 6.6
x64: .text section of ntoskrnl.exe file from Windows 7 x64: 6.5

ARM (thumb mode), Angry Birds Classic: 7.05

ARM (ARM mode) Linux Kernel 3.8.0: 6.03

MIPS (little endian), .text section of user32.dll from Windows NT 4: 6.09

So the entropy of executable code is higher than of English text, but still can be compressed.

Now the second third is started at 0xF5000. I don't know what this is. I tried different ISAs but without success. The entropy of the block looks even steadier than for executable one. Maybe some kind of data?

There is also a spike at $\approx 0x213000$. I checked it in hex editor and I found JPEG file there (which, of course, compressed)! I also don't know what is at the end. Let's try Binwalk for this file:

```
% binwalk FW96650A.bin
```

<table>

Yes, it found JPEG file and even MySQL data! But I’m not sure if it’s true—I didn’t check it yet.

It’s also interesting to try clusterization in Mathematica:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Here is an example of how Mathematica grouped various entropy values into distinctive groups. Indeed, there is something credible. Blue dots in range of 5.0-5.5 are supposedly related to English text. Yellow dots in 5.5-6 are MIPS code. A lot of green dots in 6.0-6.5 is the unknown second third. Orange dots close to 8.0 are related to compressed JPEG file. Other orange dots are supposedly related to the end of the firmware (unknown to us data).

Links

Binary files used in this part:

Wolfram Mathematica notebook file:
(all cells must be evaluated to start things working).

9.2.2 Conclusion

Information entropy can be used as a quick-n-dirty method for inspecting unknown binary files. In particular, it is a very quick way to find compressed/encrypted pieces of data. Someone say it’s possible to find RSA\(^\text{6}\) (and other asymmetric cryptographic algorithms) public/private keys in executable code (keys has high entropy as well), but I didn’t try this myself.

9.2.3 Tools

Handy Linux ent utility to measure entropy of a file\(^7\).

radare2 framework has \#entropy command for this.

A tool for IDA: IDAtropy\(^8\).

\(^8\) https://github.com/danigargu/IDAtropy

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
9.2.4 A word about primitive encryption like XORing

It’s interesting that simple XOR encryption doesn’t affect entropy of data. I’ve shown this in Norton Guide example in the book (9.1.2 on page 901).

Generalizing: encryption by substitution cipher also doesn’t affect entropy of data (and XOR can be viewed as substitution cipher). The reason of that is because entropy calculation algorithm view data on byte-level. On the other hand, the data encrypted by 2 or 4-byte XOR pattern will result in another level of entropy.

Nevertheless, low entropy is usually a good sign of weak amateur cryptography (which is also used in license keys/files, etc.).

9.2.5 More about entropy of executable code

It is quickly noticeable that probably a biggest source of high-entropy in executable code are relative offsets encoded in opcodes. For example, these two consequent instructions will have different relative offsets in their opcodes, while they are in fact pointing to the same function:

```
function proc 
...
function endp 
...
CALL function 
...
CALL function 
```

Ideal executable code compressor would encode information like this: there is a CALL to a “function” at address X and the same CALL at address Y without necessity to encode address of the function twice.

To deal with this, executable compressors are sometimes able to reduce entropy here. One example is UPX: http://sourceforge.net/p/upx/code/ci/default/tree/doc/filter.txt.

9.2.6 PRNG

When I run GnuPG to generate new private (secret) key, it asking for some entropy ...

```
We need to generate a lot of random bytes. It is a good idea to perform some other action (type on the keyboard, move the mouse, utilize the disks) during the prime generation; this gives the random number generator a better chance to gain enough entropy.

Not enough random bytes available. Please do some other work to give the OS a chance to collect more entropy! (Need 169 more bytes)
```

This means that good a PRNG produces long high-entropy results, and this is what the secret asymmetrical cryptographical key needs. But CPRNG is tricky (because computer is highly deterministic device itself), so the GnuPG asking for some additional randomness from the user.

9.2.7 More examples

Here is a case where I try to calculate entropy of some blocks with unknown contents: 8.6 on page 837.

9.2.8 Entropy of various files

Entropy of random data is close to 8:

```
% dd bs=1M count=1 if=/dev/urandom | ent
Entropy = 7.999803 bits per byte.
```

9 Cryptographically secure PseudoRandom Number Generator

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This means, almost all available space inside of byte is filled with information.

256 bytes in range of 0..255 gives exact value of 8:

```
#!/usr/bin/env python
import sys
for i in range(256):
    sys.stdout.write(chr(i))
```

```
% python 1.py | ent
Entropy = 8.000000 bits per byte.
```

Order of bytes doesn’t matter. This means, all available space inside of byte is filled.

Entropy of any block filled with zero bytes is 0:

```
% dd bs=1M count=1 if=/dev/zero | ent
Entropy = 0.000000 bits per byte.
```

Entropy of a string consisting of a single (any) byte is 0:

```
% echo -n "aaaaaaaaaaaaaaaaaaaaaaa" | ent
Entropy = 0.000000 bits per byte.
```

Entropy of base64 string is the same as entropy of source data, but multiplied by $\frac{3}{4}$. This is because base64 encoding uses 64 symbols instead of 256.

```
% dd bs=1M count=1 if=/dev/urandom | base64 | ent
Entropy = 6.022068 bits per byte.
```

Perhaps, 6.02 not that close to 6 because padding symbols (=) spoils our statistics for a little.

Uuencode also uses 64 symbols:

```
% dd bs=1M count=1 if=/dev/urandom | uuencode - | ent
Entropy = 6.013162 bits per byte.
```

This means, any base64 and Uuencode strings can be transmitted using 6-bit bytes or characters.

Any random information in hexadecimal form has entropy of 4 bits per byte:

```
% openssl rand -hex $(( 2**16 )) | ent
Entropy = 4.000013 bits per byte.
```

Entropy of randomly picked English language text from Gutenberg library has entropy $\approx 4.5$. The reason of this is because English texts uses mostly 26 symbols, and $\log_2(26) = 5.4$, i.e., you would need 5-bit bytes to transmit uncompressed English texts, that would be enough (it was indeed so in teletype era).

Randomly chosen Russian language text from http://lib.ru library is F.M.Dostoevsky “Idiot”\(^{10}\), internally encoded in CP1251 encoding.

And this file has entropy of $\approx 4.98$. Russian language has 33 characters, and $\log_2(33) \approx 5.04$. But it has unpopular and rare “ё” character. And $\log_2(32) = 5$ (Russian alphabet without this rare character)—now this close to what we’ve got.

However, the text we studying uses “ё” letter, but, probably, it’s still rarely used there.

The very same file transcoded from CP1251 to UTF-8 gave entropy of $\approx 4.23$. Each Cyrillic character encoded in UTF-8 is usually encoded as a pair, and the first byte is always one of: 0xD0 or 0xD1. Perhaps, this caused bias.

Let’s generate random bits and output them as “T” and “F” characters:

```
#!/usr/bin/env python
import random, sys
rt=""
for i in range(102400):
    if random.randint(0,1)==1:
        rt+="T"
```

\(^{10}\)http://az.lib.ru/d/dostoewskij_f_m/text_0070.shtml

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
9.2.9 Making lower level of entropy

The author of these lines once saw a software which stored each byte of encrypted data in 3 bytes: each has $\approx \frac{byte}{3}$ value, so reconstructing encrypted byte back involving summing up 3 consecutive bytes. Looks absurdly.

But some people say this was done in order to conceal the very fact the data has something encrypted inside: measuring entropy of such block will show much lower level of it.

9.3 Millenium game save file

The “Millenium Return to Earth” is an ancient DOS game (1991), that allows you to mine resources, build ships, equip them and send them on other planets, and so on\(^\text{11}\).

Like many other games, it allows you to save all game state into a file. Let's see if we can find something in it.

---

\(^{11}\)It can be downloaded for free [here](https://example.com)

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
So there is a mine in the game. Mines at some planets work faster, or slower on others. The set of resources is also different.

Here we can see what resources are mined at the time:

![Mine: State 1](image)

Figure 9.14: Mine: state 1

Let's save a game state. This is a file of size 9538 bytes.

Let's wait some “days” here in the game, and now we’ve got more resources from the mine:
Let's save game state again.

Now let’s try to just do binary comparison of the save files using the simple DOS/Windows FC utility:

```
...> FC /b 2200save.i.v1 2200SAVE.I.V2

Comparing files 2200save.i.v1 and 2200SAVE.I.V2
00000016: 0D 04
00000017: 03 04
00000146: 27 3B
00000BDA: 0E 16
00000BDC: 66 9B
00000BDE: 0E 16
00000BE0: 0E 16
00000BE6: DB 4C
00000BE7: 00 01
00000BEE: 99 E8
00000BEC: A1 F3
00000BEE: 83 C7
00000BF0: A8 28
00000BFD: 98 18
00000BFF: A8 28
00000C01: A8 28
00000C07: D8 58
00000C09: E4 A4
00000C0D: 38 B8
00000C0F: EB 68
```

The output is incomplete here, there are more differences, but we will cut result to show the most interesting.

In the first state, we have 14 “units” of hydrogen and 102 “units” of oxygen.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We have 22 and 155 “units” respectively in the second state. If these values are saved into the save file, we would see this in the difference. And indeed we do. There is 0x0E (14) at position 0xBDA and this value is 0x16 (22) in the new version of the file. This is probably hydrogen. There is 0x66 (102) at position 0xBDC in the old version and 0x9B (155) in the new version of the file. This seems to be the oxygen.

Both files are available on the website for those who wants to inspect them (or experiment) more: beginners.re.
Here is the new version of file opened in Hiew, we marked the values related to the resources mined in the game:

![Hiew: state 1](image)

Let's check each of them.

These are clearly 16-bit values: not a strange thing for 16-bit DOS software where the int type has 16-bit width.

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Let’s check our assumptions. We will write the 1234 (0x4D2) value at the first position (this must be hydrogen):

![Figure 9.17: Hiew: let’s write 1234 (0x4D2) there](image)

Then we will load the changed file in the game and took a look at mine statistics:

![Figure 9.18: Let’s check for hydrogen value](image)

So yes, this is it.
Now let’s try to finish the game as soon as possible, set the maximal values everywhere:

0xFFFF is 65535, so yes, we now have a lot of resources:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s skip some “days” in the game and oops! We have a lower amount of some resources:

![Resource variables overflow](image)

Figure 9.21: Resource variables overflow

That’s just overflow.

The game’s developer supposedly didn’t think about such high amounts of resources, so there are probably no overflow checks, but the mine is “working” in the game, resources are added, hence the overflows. Apparently, it is a bad idea to be that greedy.

There are probably a lot of more values saved in this file.

So this is very simple method of cheating in games. High score files often can be easily patched like that. More about files and memory snapshots comparing: 5.10.2 on page 724.

### 9.4 fortune program indexing file

(This part was first appeared in my blog at 25-Apr-2015.)

fortune is well-known UNIX program which shows random phrase from a collection. Some geeks are often set up their system in such way, so fortune can be called after logging on. fortune takes phrases from the text files laying in `/usr/share/games/fortunes` (as of Ubuntu Linux). Here is example (“fortunes” text file):

```
A day for firm decisions!!!!! Or is it?
%
A few hours grace before the madness begins again.
%
A gift of a flower will soon be made to you.
%
A long-forgotten loved one will appear soon.
%
Buy the negatives at any price.
%
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
A tall, dark stranger will have more fun than you.

So it is just phrases, sometimes multiline ones, divided by percent sign. The task of fortune program is to find random phrase and to print it. In order to achieve this, it must scan the whole text file, count phrases, choose random and print it. But the text file can get bigger, and even on modern computers, this naive algorithm is a bit uneconomical to computer resources. The straightforward way is to keep binary index file containing offset of each phrase in text file. With index file, fortune program can work much faster: just to choose random index element, take offset from there, set offset in text file and read phrase from it. This is actually done in fortune program. Let's inspect what is in its index file inside (these are .dat files in the same directory) in hexadecimal editor. This program is open-source of course, but intentionally, I will not peek into its source code.

Without any special aid we could see that there are four 4-byte elements on each 16-byte line. Perhaps, it's our index array. I'm trying to load the whole file in Wolfram Mathematica as 32-bit integer array:

```
In[] := BinaryReadList["c:\tmp1\fortunes.dat", "UnsignedInteger32"]
```

```
Out[] = {33554432, 2936078336, 3137339392, 251658240, 0, 37, 0, \
721420288, 1610612736, 2399141888, 3741319168, 335609856, 128025088, \
2080440320, 2868969472, 3858825216, 537001984, 989986816, 2046951424, \
3305242624, 67305472, 1023606784, 1745027072, 2801991680, 3775070208, \
419692544, 755236864, 213968576, 2902720512, 3573809152, 84213760, \
990183424, 1678049280, 2181365760, 2902786048, 3456434176, \
4144300032, 470155264, 1627783168, 2047213568, 3506831360, 168230912, \
1392967680, 2584150016, 4161208320, 654835712, 1493696512, \
2323557312, 2684878848, 3288858624, 3775397888, 4178051072, \
...}
```

Nope, something wrong. Numbers are suspiciously big. But let's back to od output: each 4-byte element has two zero bytes and two non-zero bytes, so the offsets (at least at the beginning of the file) are 16-bit at maximum. Probably different endianness is used in the file? Default endianness in Mathematica is little-endian, as used in Intel CPUs. Now I'm changing it to big-endian:

```
In[] := BinaryReadList["c:\tmp1\fortunes.dat", "UnsignedInteger32", 
ByteOrdering -> 1]
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Yes, this is something readable. I choose random element (3066) which is 0xBFA in hexadecimal form. I’m opening ‘fortunes’ text file in hex editor, I’m setting 0xBFA as offset and I see this phrase:

% od -t x1 -c --skip-bytes=0xbfa --address-radix=x fortunes
000bfa 44 6f 20 77 68 61 74 20 63 6f 6d 65 73 20 6e 61
    d o w h a t c o m e s n a
000c0a 74 75 72 61 6c 6c 79 2e 20 20 53 65 65 74 68 65
    t u r a l l y . S e e t h e
000c1a 20 61 6e 64 20 66 75 6d 65 20 61 6e 64 20 74 68
    a n d f u m e a n d t h
....

Or:

Do what comes naturally. Seethe and fume and throw a tantrum.

% od output we see that each element started with two zeros. But when shifted by two bytes in either side, we can interpret this array as little-endian:

As we can see, except of the very first 6 values (which is probably belongs to index file header), all numbers are in fact length of all text phrases (offset of the next phrase minus offset of the current phrase is in fact length of the current phrase).

It’s very important to keep in mind that bit-endiannes can be confused with incorrect array start. Indeed, from od output we see that each element started with two zeros. But when shifted by two bytes in either side, we can interpret this array as little-endian:
If we would interpret this array as little-endian, the first element is 0x4801, second is 0x7C01, etc. High 8-bit part of each of these 16-bit values are seems random to us, and the lowest 8-bit part is seems ascending.

But I'm sure that this is big-endian array, because the very last 32-bit element of the file is big-endian (00 00 5FC4 here):

Perhaps, *fortune* program developer had big-endian computer or maybe it was ported from something like it.

OK, so the array is big-endian, and, judging by common sense, the very first phrase in the text file must be started at zeroth offset. So zero value should be present in the array somewhere at the very beginning. We've got couple of zero elements at the beginning. But the second is most appealing: 43 is going right after it and 43 is valid offset to valid English phrase in the text file.

The last array element is 0x5FC4, and there are no such byte at this offset in the text file. So the last array element is pointing behind the end of file. It's supposedly done because phrase length is calculated as difference between offset to the current phrase and offset to the next phrase. This can be faster than traversing phrase string for percent character. But this wouldn't work for the last element. So the *dummy* element is also added at the end of array.

So the first 6 32-bit integer values are supposedly some kind of header.

Oh, I forgot to count phrases in text file:

```
% cat fortunes | grep % | wc -l
432
```

The number of phrases can be present in index, but may be not. In case of very simple index files, number of elements can be easily deduced from index file size. Anyway, there are 432 phrases in the text file. And we see something very familiar at the second element (value 431). I've checked other files (literature.dat and riddles.dat in Ubuntu Linux) and yes, the second 32-bit element is indeed number of phrases minus 1. Why *minus* 1? Perhaps, this is not number of phrases, but rather the number of the last phrase (starting at zero)?

And there are some other elements in the header. In Mathematica, I'm loading each of three available files and I'm taking a look on the header:

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
I have no idea what other values mean, except the size of index file. Some fields are the same for all files, some are not. From my own experience, there could be:

- file signature;
- file version;
- checksum;
- some flags;
- maybe even text language identifier;
- text file timestamp, so the fortune program will regenerate index file if a user modified text file.

For example, Oracle .SYM files (9.5 on the following page) which contain symbols table for DLL files, also contain timestamp of corresponding DLL file, so to be sure it is still valid.

On the other hand, text file and index file timestamps can gone out of sync after archiving/unarchiving/installing/deploying/etc.

But there are no timestamp, in my opinion. The most compact way of representing date and time is UNIX time value, which is big 32-bit number. We don’t see any of such here. Other ways of representation are even less compact.

So here is algorithm, how fortune supposedly works:

- take number of last phrase from the second element;
- generate random number in range of 0..number_of_last_phrase;
- find corresponding element in array of offsets, take also following offset;
- output to stdout all characters from the text file starting at the offset until the next offset minus 2 (so to ignore terminating percent sign and character of the following phrase).

### 9.4.1 Hacking

Let’s try to check some of our assumptions. I will create this text file under the path and name /usr/share/games/fortunes/fortunes:

<table>
<thead>
<tr>
<th>Phrase one.</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
</tr>
<tr>
<td>Phrase two.</td>
</tr>
<tr>
<td>%</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Then this fortunes.dat file. I take header from the original fortunes.dat, I changed second field (count of all phrases) to zero and I left two elements in the array: 0 and 0x1c, because the whole length of the text fortunes file is 28 (0x1c) bytes:

```
% od -t x1 --address-radix=x fortunes.dat
000000 00 00 00 02 00 00 00 00 00 00 bb 00 00 00 0f
00010 00 00 00 00 25 00 00 00 00 00 00 00 00 00 1c
```

Now I run it:

```
% /usr/games/fortune
fortune: no fortune found
```

Something wrong. Let's change the second field to 1:

```
% od -t x1 --address-radix=x fortunes.dat
000000 00 00 00 02 00 00 00 00 00 00 01 00 00 00 bb 00 00 00 0f
00010 00 00 00 00 25 00 00 00 00 00 00 00 00 00 1c
```

Now it works. It's always shows only the first phrase:

```
% /usr/games/fortune
Phrase one.
```

Hmmm. Let's leave only one element in array (0) without terminating one:

```
% od -t x1 --address-radix=x fortunes.dat
000000 00 00 00 02 00 00 00 00 00 00 01 00 00 00 bb 00 00 00 0f
000010 00 00 00 00 25 00 00 00 00 00 00 00 00 00 00
```

Fortune program always shows only first phrase.

From this experiment we got to know that percent sign in text file is parsed and the size is not calculated as I deduced before, perhaps, even terminal array element is not used. However, it still can be used. And probably it was used in past?

### 9.4.2 The files

For the sake of demonstration, I still didn’t take a look in fortune source code. If you want to try to understand meaning of other values in index file header, you may try to achieve it without looking into source code as well. Files I took from Ubuntu Linux 14.04 are here: [http://beginners.re/examples/fortune/](http://beginners.re/examples/fortune/), hacked files are also here.

Oh, and I took the files from x64 version of Ubuntu, but array elements are still has size of 32 bit. It is because fortune text files are probably never exceeds 4GiB size. But if it will, all elements must have size of 64 bit so to be able to store offset to the text file larger than 4GiB.

For impatient readers, the source code of fortune is here: [https://launchpad.net/ubuntu/+source/fortune-mod/1:1.99.1-3.1ubuntu4](https://launchpad.net/ubuntu/+source/fortune-mod/1:1.99.1-3.1ubuntu4).

### 9.5 Oracle RDBMS: .SYM-files

When an Oracle RDBMS process experiences some kind of crash, it writes a lot of information into log files, including stack trace, like this:

```
----- Call Stack Trace ----- 
calling location argument values in hex
call entry type point 
------------------------- ------------------- -------------- 
_kqvrow() 00000000 (?? means dubious value)
_opifch2()+2729 CALLptr 00000000 23D4B914 E47F264 1F19AE2
_kpoal8()+2832 CALLrel _opifch2() 00 000000 89 5 EB1CC74
```

For statistics collecting purposes) if you’ve read this far, please click [here](https://launchpad.net/ubuntu/+source/fortune-mod/1:1.99.1-3.1ubuntu4). Thanks!
But of course, Oracle RDBMS’s executables must have some kind of debug information or map files with symbol information included or something like that.

Windows NT Oracle RDBMS has symbol information in files with .SYM extension, but the format is proprietary. (Plain text files are good, but needs additional parsing, hence offer slower access.)

Let’s see if we can understand its format.

We will pick the shortest orawtc8.sym file that comes with the orawtc8.dll file in Oracle 8.1.7 13.

---

13We can chose an ancient Oracle RDBMS version intentionally due to the smaller size of its modules.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
By comparing the file with other .SYM files, we can quickly see that OSYM is always header (and footer), so this is maybe the file’s signature.

We also see that basically, the file format is: OSYM + some binary data + zero delimited text strings + OSYM. The strings are, obviously, function and global variable names.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We will mark the OSYM signatures and strings here:

Well, let’s see. In Hiew, we will mark the whole strings block (except the trailing OSYM signatures) and put it into a separate file. Then we run UNIX `strings` and `wc` utilities to count the text strings:

```
strings strings_block | wc -l
66
```

So there are 66 text strings. Please note that number.

We can say, in general, as a rule, the number of anything is often stored separately in binary files.

It’s indeed so, we can find the 66 value (0x42) at the file’s start, right after the OSYM signature:

```
$ hexdump -C orawtc8.sym
```

Of course, 0x42 here is not a byte, but most likely a 32-bit value packed as little-endian, hence we see 0x42 and then at least 3 zero bytes.

Why do we believe it’s 32-bit? Because, Oracle RDBMS’s symbol files may be pretty big.

The oracle.sym file for the main oracle.exe (version 10.2.0.4) executable contains 0x3A38E (238478) symbols. A 16-bit value isn’t enough here.

We can check other .SYM files like this and it proves our guess: the value after the 32-bit OSYM signature always reflects the number of text strings in the file.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
It's a general feature of almost all binary files: a header with a signature plus some other information about the file.

Now let's investigate closer what this binary block is.

Using Hiew again, we put the block starting at address 8 (i.e., after the 32-bit count value) ending at the strings block, into a separate binary file.
Let's see the binary block in Hiew:

Figure 9.24: Binary block

There is a clear pattern in it.
We will add red lines to divide the block:

Figure 9.25: Binary block patterns

Hiew, like almost any other hexadecimal editor, shows 16 bytes per line. So the pattern is clearly visible: there are 4 32-bit values per line.

The pattern is visually visible because some values here (till address 0x104) are always in 0x1000xxxx form, started with 0x10 and zero bytes.

Other values (starting at 0x108) are in 0x0000xxxx form, so always started with two zero bytes.

Let's dump the block as an array of 32-bit values:

Listing 9.9: first column is address

```
$ od -v -t x4 binary_block
00000000  10 00 10 80 10 00 10 FO 00 10 50 11 00 10     
00000100  60 11 00 10 C0 11 00 10 D0 11 00 10 70 13 00 10

00001900  3D 02 00 00 04 02 00 00 06 02 00 00 07 02 00 00     
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
There are 132 values, that’s 66*2. Probably, there are two 32-bit values for each symbol, but maybe there are two arrays? Let’s see.

Values starting with 0x1000 may be addresses.

This is a .SYM file for a DLL after all, and the default base address of win32 DLLs is 0x10000000, and the code usually starts at 0x10001000.

When we open the orawtc8.dll file in IDA, the base address is different, but nevertheless, the first function is:

```
.text:60351000 sub_60351000 proc near
.text:60351000
.text:60351000 arg_0 = dword ptr 8
.text:60351000 arg_4 = dword ptr 0Ch
.text:60351000 arg_8 = dword ptr 10h
.text:60351000
.text:60351000 push ebp
.text:60351001 mov ebp, esp
.text:60351003 mov eax, dword_60353014
.text:60351008 cmp eax, 0FFFFFFFFh
.text:60351008 jnz short loc_6035104F
.text:6035100d mov ecx, hModule
.text:60351013 xor eax, eax
.text:60351015 cmp ecx, 0FFFFFFFFh
.text:60351018 mov dword_60353014, eax
.text:6035101d jnz short loc_60351031
.text:6035101f call sub_603510F0
.text:60351024 mov ecx, eax
.text:60351026 mov eax, dword_60353014
.text:60351028 mov hModule, ecx
.text:60351031 loc_60351031: ; CODE XREF: sub_60351000+1D
.text:60351031 test ecx, ecx
.text:60351033 jbe short loc_6035104F
.text:60351035 push offset ProcName ; "ax_reg"
.text:6035103A push ecx ; hModule
.text:6035103B call ds:GetProcAddress
```

Wow, “ax_reg” string sounds familiar.

It’s indeed the first string in the strings block! So the name of this function seems to be “ax_reg”.

The second function is:
The “ax_unreg” string is also the second string in the strings block!

The starting address of the second function is 0x60351080, and the second value in the binary block is 10001080. So this is the address, but for a DLL with the default base address.

We can quickly check and be sure that the first 66 values in the array (i.e., the first half of the array) are just function addresses in the DLL, including some labels, etc. Well, what’s the other part of array then? The other 66 values that start with 0x0000? These seem to be in range [0...0x3F8]. And they do not look like bitfields: the series of numbers is increasing.

The last hexadecimal digit seems to be random, so, it’s unlikely the address of something (it would be divisible by 4 or maybe 8 or 0x10 otherwise).

Let’s ask ourselves: what else Oracle RDBMS’s developers would save here, in this file?

Quick wild guess: it could be the address of the text string (function name).

It can be quickly checked, and yes, each number is just the position of the first character in the strings block.

This is it! All done.

We will write an utility to convert these .SYM files into IDA script, so we can load the .idc script and it sets the function names:

```c
#include <stdio.h>
#include <stdint.h>
#include <io.h>
#include <assert.h>
#include <malloc.h>
#include <fcntl.h>
#include <string.h>

int main (int argc, char *argv[]) {
    uint32_t sig, cnt, offset;
    uint32_t *d1, *d2;
    int h, i, remain, file_len;
    char *d3;
    uint32_t array_size_in_bytes;

    assert (argv[1]); // file name
    assert (argv[2]); // additional offset (if needed)
```
// additional offset
assert (sscanf (argv[2], "%X", &offset)==1);

// get file length
assert ((fopen (argv[1], _O_RDONLY | _O_BINARY, 0))!=0);
assert ((file_len=lseek (h, 0, SEEK_END))!=-1);
assert (lseek (h, 0, SEEK_SET)!=-1);

// read signature
assert (read (h, &sig, 4)==4);
// read count
assert (sig==0x4D59534F); // OSYM

// skip timedatestamp (for 11g)
// _lseek (h, 4, 1);

array_size_in_bytes=cnt*sizeof(uint32_t);

// load symbol addresses array
d1=(uint32_t*)malloc (array_size_in_bytes);
assert (d1);
assert (read (h, d1, array_size_in_bytes)==array_size_in_bytes);

// load string offsets array
d2=(uint32_t*)malloc (array_size_in_bytes);
assert (d2);
assert (read (h, d2, array_size_in_bytes)==array_size_in_bytes);

// calculate strings block size
remain=file_len-(8+4)-(cnt*8);

// load strings block
assert (d3=(char*)malloc (remain));
assert (read (h, d3, remain)==remain);

printf ("#include <idc.idc>\n\n");
printf ("static main () {\n");

for (i=0; i<cnt; i++)
printf ("\tMakeName(0x%08X, "%s");\n", offset + d1[i], &d3[d2[i]])
printf ("");

close (h);
free (d1); free (d2); free (d3);
}

Here is an example of its work:

#include <idc.idc>

static main () {
    MakeName(0x60351000, "_ax_reg");
    MakeName(0x60351080, "_ax_unreg");
    MakeName(0x603510F0, "_loaddll");
    MakeName(0x60351150, "_wtcsrin0");
    MakeName(0x60351160, "_wtcsrin");
    MakeName(0x603511C0, "_wtcsrfree");
    MakeName(0x603511D0, "_wtclkm");
    MakeName(0x60351370, "_wtcstu");
    ...
}

The example files were used in this example are here: beginners.re.
Oh, let’s also try Oracle RDBMS for win64. There has to be 64-bit addresses instead, right?

The 8-byte pattern is visible even easier here:

![Figure 9.26: .SYM-file example from Oracle RDBMS for win64](image)

So yes, all tables now have 64-bit elements, even string offsets!

The signature is now OSYMAM64, to distinguish the target platform, apparently.

This is it!

Here is also library which has functions to access Oracle RDBMS.SYM-files: [GitHub](https://github.com).

### 9.6 Oracle RDBMS: .MSB-files

This is a binary file that contains error messages with their corresponding numbers. Let’s try to understand its format and find a way to unpack it.

---

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
There are Oracle RDBMS error message files in text form, so we can compare the text and packed binary files.

This is the beginning of the ORAUS.MSG text file with some irrelevant comments stripped:

Listing 9.10: Beginning of ORAUS.MSG file without comments

```
00000, 00000, "normal, successful completion"
00001, 00000, "unique constraint (%s.%s) violated"
00017, 00000, "session requested to set trace event"
00018, 00000, "maximum number of sessions exceeded"
00019, 00000, "maximum number of session licenses exceeded"
00020, 00000, "maximum number of processes (%s) exceeded"
00021, 00000, "session attached to some other process; cannot switch session"
00022, 00000, "invalid session ID; access denied"
00023, 00000, "session references process private memory; cannot detach session"
00024, 00000, "logins from more than one process not allowed in single-process mode"
00025, 00000, "failed to allocate %s"
00026, 00000, "missing or invalid session ID"
00027, 00000, "cannot kill current session"
00028, 00000, "your session has been killed"
00029, 00000, "session is not a user session"
00030, 00000, "User session ID does not exist."
00031, 00000, "session marked for kill"
...```

The first number is the error code. The second is perhaps maybe some additional flags.

---

14 Open-source text files don’t exist in Oracle RDBMS for every .MSB file, so that’s why we will work on their file format (For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Now let’s open the ORAUS.MSG binary file and find these text strings. And there are:

Figure 9.27: Hiew: first block

We see the text strings (including those from the beginning of the ORAUS.MSG file) interleaved with some binary values. By quick investigation, we can see that main part of the binary file is divided by blocks of size 0x200 (512) bytes.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let’s see the contents of the first block:

![Image](image-url)  

Here we see the texts of the first messages errors. What we also see is that there are no zero bytes between the error messages. This implies that these are not null-terminated C strings. As a consequence, the length of each error message must be encoded somehow. Let’s also try to find the error numbers. The ORAUS.MSG files starts with these: 0, 1, 17 (0x11), 18 (0x12), 19 (0x13), 20 (0x14), 21 (0x15), 22 (0x16), 23 (0x17), 24 (0x18)... We will find these numbers at the beginning of the block and mark them with red lines. The period between error codes is 6 bytes.

This implies that there are probably 6 bytes of information allocated for each error message.

The first 16-bit value (0xA here or 10) means the number of messages in each block: this can be checked by investigating other blocks. Indeed: the error messages have arbitrary size. Some are longer, some are shorter. But block size is always fixed, hence, you never know how many text messages can be packed in each block.

As we already noted, since these are not null-terminated C strings, their size must be encoded somewhere. The size of the first string “normal, successful completion” is 29 (0x1D) bytes. The size of the second string “unique constraint (%s.%s) violated” is 34 (0x22) bytes. We can’t find these values (0x1D or/and 0x22) in the block.

There is also another thing. Oracle RDBMS has to determine the position of the string it needs to load in the block, right? The first string “normal, successful completion” starts at position 0x1444 (if we count starting at the beginning of the file) or at 0x44 (from the block’s start). The second string “unique constraint

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
(\%s.\%s) violated" starts at position 0x1461 (from the file’s start) or at 0x61 (from the at the block’s start). These numbers (0x44 and 0x61) are familiar somehow! We can clearly see them at the start of the block.

So, each 6-byte block is:

- 16-bit error number;
- 16-bit zero (maybe additional flags);
- 16-bit starting position of the text string within the current block.

We can quickly check the other values and be sure our guess is correct. And there is also the last “dummy” 6-byte block with an error number of zero and starting position beyond the last error message’s last character. Probably that’s how text message length is determined? We just enumerate 6-byte blocks to find the error number we need, then we get the text string’s position, then we get the position of the text string by looking at the next 6-byte block! This way we determine the string’s boundaries! This method allows to save some space by not saving the text string’s size in the file!

It’s not possible to say it saves a lot of space, but it’s a clever trick.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Let's back to the header of .MSB-file:

Figure 9.29: Hiew: file header

Now we can quickly find the number of blocks in the file (marked by red). We can checked other .MSB-files and we see that it’s true for all of them.

There are a lot of other values, but we will not investigate them, since our job (an unpacking utility) is done.

If we have to write a .MSB file packer, we would probably have to understand the meaning of the other values.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
There is also a table that came after the header which probably contains 16-bit values:

<table>
<thead>

</table>

Figure 9.30: Hiew: last_errno table

Their size can be determined visually (red lines are drawn here).

While dumping these values, we have found that each 16-bit number is the last error code for each block.

So that’s how Oracle RDBMS quickly finds the error message:

- load a table we will call last_errno (that contains the last error number for each block);
- find a block that contains the error code we need, assuming all error codes increase across each block and across the file as well;
- load the specific block;
- enumerate the 6-byte structures until the specific error number is found;
- get the position of the first character from the current 6-byte block;
- get the position of the last character from the next 6-byte block;
- load all characters of the message in this range.

This is C program that we wrote which unpacks .MSB-files: beginners.re.

There are also the two files which were used in the example (Oracle RDBMS 11.1.0.6): beginners.re, beginners.re.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
9.6.1 Summary

The method is probably too old-school for modern computers. Supposedly, this file format was developed in the mid-80’s by someone who also coded for big iron with memory/disk space economy in mind. Nevertheless, it has been an interesting and yet easy task to understand a proprietary file format without looking into Oracle RDBMS’s code.

9.7 Exercises

Try to reverse engineer of any binary files of your favorite game, including high-score files, resources, etc. There are also binary files with known structure: utmp/wtmp files, try to understand its structure without documentation.

The EXIF header in JPEG file is documented, but you can try to understand its structure without help, just shoot photos at various date/time, places, and try to find date/time and GPS location in EXIF. Try to patch GPS location, upload JPEG file to Facebook and see, how it will put your picture on the map.

Try to patch any information in MP3 file and see how your favorite MP3-player will react.

Chapter 10

Dynamic binary instrumentation

DBI tools can be viewed as highly advanced and fast debuggers.

10.1 Using PIN DBI for XOR interception

PIN from Intel is a DBI tool. That means, it takes compiled binary and inserts your instructions in it, where you want.

Let's try to intercept all XOR instructions. These are heavily used in cryptography, and we can try to run WinRAR archiver in encryption mode with a hope that some XOR instruction is indeed is used while encryption.

Here is the source code of my PIN tool: https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/XOR/files/XOR_ins.cpp.

The code is almost self-explanatory: it scans input executable file for all XOR/PXOR instructions and inserts a call to our function before each. log_info() function first checks, if operands are different (since XOR is often used just to clear register, like XOR EAX, EAX), and if they are different, it increments a counter at this EIP/RIP, so the statistics will be gathered.

I have prepared two files for test: test1.bin (30720 bytes) and test2.bin (5547752 bytes), I’ll compress them by RAR with password and see difference in statistics.

You’ll also need to turn off ASLR, so the PIN tool will report the same RIPS as in RAR executable.

Now let’s run it:

```
c:\pin-3.2-81205-msvc-windows\pin.exe -t XOR_ins.dll -- rar a -pLongPassword tmp.rar test1.bin
c:\pin-3.2-81205-msvc-windows\pin.exe -t XOR_ins.dll -- rar a -pLongPassword tmp.rar test2.bin
```

Now here is statistics for the test1.bin:

https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/XOR/files/XOR_ins.out

... and for test2.bin:

https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/XOR/files/XOR_ins.out
test2. So far, you can ignore all addresses other than ip=0x1400xxxxx, which are in other DLLs.

Now let’s see a difference: https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/XOR/files/XOR_ins.diff

Some XOR instructions are executed more often for test2.bin (which is bigger) than for test1.bin (which is smaller). So these are clearly related to file size!

The first block of differences is:

```
< ip=0x140017b21 count=0xd84
< ip=0x140017b48 count=0x81f
< ip=0x140017b59 count=0x858
< ip=0x140017b6a count=0xc13
< ip=0x140017b7b count=0xefc
< ip=0x140017b8a count=0xefd
< ip=0x140017b92 count=0xb86
```

1https://stackoverflow.com/q/9560993
This is indeed some kind of loop inside of RAR.EXE:

```
.text:0000000140017B21 loc_140017B21:
.xor r11d, [rbx]
.mov r9d, [rbx+4]
.add rbx, 8
.mov eax, r9d
.shr eax, 18h
.movsx edx, al
.mov eax, r9d
.shr eax, 10h
.movzx ecx, al
.mov eax, r9d
.shr eax, 8
.mov r8d, [rsi+rdx*4]
.xor r8d, [rsi+rcx*4+400h]
.movzx ecx, al
.mov eax, r11d
.shr eax, 18h
.xor r8d, [rsi+rcx*4+800h]
.movzx ecx, al
.mov eax, r11d
.shr eax, 10h
.xor r8d, [rsi+rcx*4+1000h]
.movzx ecx, al
.mov eax, r11d
.shr eax, 8
.xor r8d, [rsi+rcx*4+1400h]
.movzx ecx, al
.mov eax, r9b
.xor r8d, [rsi+rcx*4+1800h]
.xor r8d, [rsi+rax*4+0C00h]
.movzx eax, r11b
.mov r11d, r8d
.xor r11d, [rsi+rax*4+1C00h]
.sub rdi, 1
.jnz loc_140017B21
```

What does it do? No idea yet.

The next:

```
< ip=0x14002c4f1 count=0x4fce ...
> ip=0x14002c4f1 count=0x4463be
```

0x4fce is 20430, which is close to size of test1.bin (30720 bytes). 0x4463be is 4481982 which is close to size of test2.bin (5547752 bytes). Not equal, but close.

This is a piece of code with that XOR instruction:

```
.text:0000000140017B21 loc_140017B21:
.movzx eax, byte ptr [r8]
.shl ecx, 5
.xor ecx, eax
.and ecx, 7FFFh
.cmp [r11+rcx*4], esi
.jb short loc_14002C507
.cmp [r11+rcx*4], r10d
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
Loop body can be written as:

\[ \text{state} = \text{input-byte} \oplus (\text{state} \ll 5) \land 0x7FFF. \]

\( \text{state} \) is then used as index in some table. Is this some kind of CRC\(^2\)? I don’t know, but this could be a checksumming routine. Or maybe optimized CRC routine? Any ideas?

The next block:

< ip=0x14004104a count=0x367  
< ip=0x140041057 count=0x367  
...  
> ip=0x14004104a count=0x24193  
> ip=0x140041057 count=0x24193

This piece has both PXOR and AESSNCE instructions (the last is AES\(^3\) encryption instruction). So yes, we found encryption function, RAR uses AES.

There is also another big block of almost contiguous XOR instructions:

< ip=0x140043e10 count=0x23006  
...  
> ip=0x140043e10 count=0x23004  
499c510  
< ip=0x140043e56 count=0x22ffd  
...  
> ip=0x140043e56 count=0x23002

But, its count is not very different during compressing/encrypting test1.bin/test2.bin. What is on these addresses?

\(^2\)Cyclic redundancy check  
\(^3\)Advanced Encryption Standard
Let's google 5A827999h constant... this looks like SHA-1! But why would RAR use SHA-1 during encryption?

Here is the answer:

In comparison, WinRAR uses its own key derivation scheme that requires (password length * 2 + \(11\)*4096 SHA-1 transformations. That's why it takes longer to brute-force attack encrypted WinRAR archives.

(http://www.tomshardware.com/reviews/password-recovery-gpu,2945-8.html)

This is key scheduling: input password hashed many times and the hash is then used as AES key. This is why we see the count of XOR instruction is almost unchanged during we switched to bigger test file.

This is it, it took couple of hours for me to write this tool and to get at least 3 points: 1) probably checksumming; 2) AES encryption; 3) SHA-1 calculation. The first function is still unknown for me.

Still, this is impressive, because I didn't dig into RAR code (which is proprietary, of course). I didn't even peek into UnRAR source code (which is available).

The files, including test files and RAR executable I've used (win64, 5.40):
https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/XOR/files

10.2 Cracking Minesweeper with PIN

In this book, I wrote about cracking Minesweeper for Windows XP: 8.3 on page 802.

The Minesweeper in Windows Vista and 7 is different: probably it was (re)written to C++, and a cell information is now stored not in global array, but rather in malloc’ed heap blocks.

This is a case when we can try PIN DBI tool.

10.2.1 Intercepting all rand() calls

First, since Minesweeper places mines randomly, it has to call rand() or similar function. Let’s intercept all rand() calls:

Now we can run it:

```
c:\pin-3.2-81205-msvc-windows\pin.exe -t minesweeper1.dll -- C:\PATH\TO\MineSweeper.exe
```

During startup, PIN searches for all calls to rand() function and adds a hook right after each call. The hook is the RandAfter() function we defined: it is logging about return value and also about return address. Here is a log I got during run of standard 9*9 configuration (10 mines):
https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/minesweeper/minesweeper1.out.10mines. The rand() function was called many times from several places, but was called from 0x10002770d just 10 times. I switched Minesweeper to 16*16 configuration (40 mines) and rand() was called from 0x10002770d 40 times. So yes, this is our point. When I load minesweeper.exe (from Windows 7) into IDA and PDB from Microsoft website is fetched, the function which calls rand() at 0x10002770d called Board::place Mines().

10.2.2 Replacing rand() calls with our function

Let’s now try to replace rand() function with our version, let it always return zero:
https://github.com/DennisYurichev/RE-for-beginners/tree/master/DBI/minesweeper/minesweeper2.cpp. During startup, PIN replaces all calls to rand() to calls to our function, which writes to log and returns zero. OK, I run it, and clicked on leftmost/topmost cell:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Yes, unlike Minesweeper from Windows XP, mines are places randomly after user’s click on cell, so to guarantee there is no mine at the cell user first clicked. So Minesweeper placed mines on cells other than leftmost/topmost (where I clicked).

Now I clicked on rightmost/topmost cell:

This can be some kind of practical joke? I don’t know.

I clicked on 5th cell (right at the middle) at the 1st row:

This is nice, because Minesweeper can do some correct placement even with such a broken **PRNG**!
10.2.3 Peeking into placement of mines

How can we get information about where mines are placed? rand()'s result is seems to be useless: it returned zero all the time, but Minesweeper somehow managed to place mines in different cells, though, lined up.

This Minesweeper also written in C++ tradition, so it has no global arrays.

Let us put ourselves in the position of programmer. It has to be loop like:

```cpp
for (int i; i<mines_total; i++)
{
    // get coordinates using rand()
    // put a cell: in other words, modify a block allocated in heap

    // get coordinates using rand()
    // put a cell: in other words, modify a block allocated in heap
}
```

How can we get information about heap block which gets modified at the 2nd step? What we need to do:

1) track all heap allocations by intercepting malloc()/reallocate()/free().
2) track all memory writes (slow).
3) intercept calls to rand().

Now the algorithm: 1) mark all heap blocks gets modified between 1st and 2nd call to rand() from 0x10002770d; 2) whenever heap block gets freed, dump its contents.

Tracking all memory writes is slow, but after 2nd call to rand(), we don’t need to track it (since we’ve got already a list of blocks of interest at this point), so we turn it off.

As it turns out, only 4 heap blocks gets modified between first two rand() calls, this is how they looks like:

```c
free(0x20aaa6360)
free(): we have this block in our records, size=0x28

0x20B28BC0: 50 00 00 00 50 00 00 00-50 00 00 00 50 00 00 00 "P...P...P...P..."
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
We can easily see that the biggest blocks (with size 0x28 and 0x140) are just arrays of values up to ~ 0x50. Wait... 0x50 is 80 in decimal representation. And 9*9=81 (standard minesweeper configuration).

After quick investigation, I've found that each 32-bit element is indeed cell coordinate. A cell is represented using a single number, it's a number inside of 2D-array. Row and column of each mine is decoded like that: row=n/WIDTH; col=n % HEIGHT;

So when I tried to decode these two biggest blocks, I've got these cell maps:

```
try_to_dump_cells(). unique elements=0xa
......*..
...........
...........
...........
*........*
**........
...........
...........
......*..
...

try_to_dump_cells(). unique elements=0x44
********
*****.***
..*******
*******.*
*********
*****.***
..*******
*******.*
******.**
```

It seems that the first block is just a list of mines placed, while the second block is a list of free cells, but, the second is somewhat out of sync with the first one, and it's negative version of the first one coincides only partially. Nevertheless, the first map is correct - we can peek into it in log file when Minesweeper is still loaded and almost all cells are hidden, and click safely on cells marked as dots here.

So it seems, when user first clicked somewhere, Minesweeper places 10 mines, than destroys the block with a list of it (perhaps, it copies all the data to another block before?), so we can see it during free() call.

Another fact: the method Array<NodeType>::Add(NodeType) modifies blocks we observed, and is called from various places, including Board::placeMines(). But what is cool: I never got into its details, everything has been resolved using just PIN.

### 10.2.4 Exercise

Try to understand how rand()'s result being converted into coordinate(s). As a practical joke, make rand() to output such results, so mines will be placed in shape of some symbol or figure.

### 10.3 Building Pin

Building Pin for Windows may be tricky. This is my working recipe.

- Unpack latest Pin to, say, C:\pin-3.7
- Install latest Cygwin, to, say, c:\cygwin64
- Install MSVC 2015 or newer.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Open file `C:\pin-3.7\source\tools\Config\makefile.default.rules`, replace `mkdir -p $@` to `/bin/mkdir -p $@`

(If needed) in `C:\pin-3.7\source\tools\SimpleExamples\makefile.rules`, add your pintool to the TEST_TOOL_ROOTS list.

Open “VS2015 x86 Native Tools Command Prompt”. Type:
```
cd c:\pin-3.7\source\tools\SimpleExamples
c\cygwin64\bin\make all TARGET=ia32
```
Now pintools are in `c:\pin-3.7\source\tools\SimpleExamples\obj-ia32`

For winx64, use “x64 Native Tools Command Prompt” and run:
```
c:\cygwin64\bin\make all TARGET=intel64
```

Run pintool:
```
c:\pin-3.7\pin.exe -t C:\pin-3.7\source\tools\SimpleExamples\obj-ia32\XOR_ins.dll -- ∫ program.exe arguments
```

10.4 Why “instrumentation”?

Perhaps, this is a term of code profiling. There are at least two methods: 1) “sampling”: you break into running code as many times as possible (hundreds per second), and see, where it is executed at the moment; 2) “instrumentation”: compiled code is interleaved with other code, which can increment counters, etc.

Perhaps, DBI tools inherited the term?
Chapter 11

Other things

11.1 Executable files patching

11.1.1 Text strings

The C strings are the thing that is the easiest to patch (unless they are encrypted) in any hex editor. This technique is available even for those who are not aware of machine code and executable file formats. The new string has not to be bigger than the old one, because there’s a risk of overwriting another value or code there.

Using this method, a lot of software was localized in the MS-DOS era, at least in the ex-USSR countries in 80’s and 90’s. It was the reason why some weird abbreviations were present in the localized software: there was no room for longer strings.

As for Delphi strings, the string’s size must also be corrected, if needed.

11.1.2 x86 code

Frequent patching tasks are:

- One of the most frequent jobs is to disable some instruction. It is often done by filling it using byte 0x90 (NOP).
- Conditional jumps, which have an opcode like 74 xx (JZ), can be filled with two NOPs.
  It is also possible to disable a conditional jump by writing 0 at the second byte (jump offset).
- Another frequent job is to make a conditional jump to always trigger: this can be done by writing 0xEB instead of the opcode, which stands for JMP.
- A function’s execution can be disabled by writing RETN (0xC3) at its beginning. This is true for all functions excluding stdcall (6.1.2 on page 733). While patching stdcall functions, one has to determine the number of arguments (for example, by finding RETN in this function), and use RETN with a 16-bit argument (0xC2).
- Sometimes, a disabled functions has to return 0 or 1. This can be done by MOV EAX, 0 or MOV EAX, 1, but it’s slightly verbose.
  A better way is XOR EAX, EAX (2 bytes 0x31 0xC0) or XOR EAX, EAX / INC EAX (3 bytes 0x31 0xC0 0x40).

A software may be protected against modifications.

This protection is often done by reading the executable code and calculating a checksum. Therefore, the code must be read before protection is triggered.

This can be determined by setting a breakpoint on reading memory.

tracer has the BPM option for this.

PE executable file relocs (6.5.2 on page 759) must not to be touched while patching, because the Windows loader may overwrite your new code. (They are grayed in Hiew, for example: fig.1.22).
As a last resort, it is possible to write jumps that circumvent the relocations, or you will have to edit the relocations table.

11.2 Function arguments number statistics

I've always been interesting in what is average number of function arguments.

I've analyzed many Windows 7 32-bit DLLs (crypt32.dll, mfc71.dll, msvcr100.dll, shell32.dll, user32.dll, d3d11.dll, mshtml.dll, msxml6.dll, sqlncli11.dll, wininet.dll, mfc120.dll, msvbvm60.dll, ole32.dll, themeui.dll, wmp.dll) (because they use *stdcall* convention, and so it is easy to *grep* disassembly output just by RETN X).

- no arguments: ≈ 29%
- 1 argument: ≈ 23%
- 2 arguments: ≈ 20%
- 3 arguments: ≈ 11%
- 4 arguments: ≈ 7%
- 5 arguments: ≈ 3%
- 6 arguments: ≈ 2%
- 7 arguments: ≈ 1%

![Figure 11.1: Function arguments number statistics](image)

This is heavily dependent on programming style and may be very different for other software products.

11.3 Compiler intrinsic

A function specific to a compiler which is not an usual library function. The compiler generates a specific machine code instead of a call to it. It is often a pseudofunction for specific CPU instruction.

For example, there are no cyclic shift operations in C/C++ languages, but they are present in most CPUs.

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
For programmer’s convenience, at least MSVC has pseudofunctions \_\rotl() and \_\rotr() which are translated by the compiler directly to the ROL/ROR x86 instructions.

Another example are functions to generate SSE-instructions right in the code.

Full list of MSVC intrinsics: MSDN.

### 11.4 Compiler’s anomalies

#### 11.4.1 Oracle RDBMS 11.2 and Intel C++ 10.1

Intel C++ 10.1, which was used for Oracle RDBMS 11.2 Linux86 compilation, may emit two JZ in row, and there are no references to the second JZ. The second JZ is thus meaningless.

Listing 11.1: kdli.o from libserver11.a

```plaintext

.loc_8114D1A 50          push    eax
.loc_8114D1B 52          push    edx
.loc_8114D1C E8 03 54 00 00  call    len2nbytes
.loc_8114D21 83 C4 08          add     esp, 8
```

Listing 11.2: from the same code

```plaintext
.loc_811A2A5: ; CODE XREF: kdliSerLengths+11C
.loc_811A2A5: ; kdliSerLengths+1C
.text:0811A2A5
.loc_811A2A5 8B 45 08          mov    edi, [ebp+arg_0]
.loc_811A2A8 8B 7F 10          mov    edi, [edi+10h]
.loc_811A2AB 0F B6 57 14          movzx   edx, byte ptr [edi+14h]
.loc_811A2AF F6 C2 01          test    dl, 1
.loc_811A2B2 75 3E          jnz     short loc_811A2F2
.loc_811A2B4 83 E0 01          and     eax, 1
.loc_811A2B7 74 1F          jz      short loc_811AD08
.loc_811A2B9 74 37          jz      short loc_811AD2F
.loc_811A2BB 6A 00          push    0
.loc_811A2BD FF 71 08          push    dword ptr [ecx+8]
.loc_811A2C0 EB 5F FF FF FF          call    len2nbytes
```

It is supposedly a code generator bug that was not found by tests, because resulting code works correctly anyway.

#### 11.4.2 MSVC 6.0

Just found in some old code:

```plaintext
fabs
fild [esp+50h+var_34]
fabs
fxch st(1) ; first instruction
fxch st(1) ; second instruction
faddp st(1), st
```

1 MSDN

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
The first FXCH instruction swaps ST(0) and ST(1), the second do the same, so both do nothing. This is a program uses MFC42.dll, so it could be MSVC 6.0, 5.0 or maybe even MSVC 4.2 from 1990s. This pair do nothing, so it probably wasn’t caught by MSVC compiler tests. Or maybe I wrong?

11.4.3 Summary

Other compiler anomalies here in this book: 1.28.2 on page 318, 3.8.3 on page 500, 3.16.7 on page 539, 1.26.7 on page 303, 1.18.4 on page 147, 1.28.5 on page 335.

Such cases are demonstrated here in this book, to show that such compilers errors are possible and sometimes one should not to rack one’s brain while thinking why did the compiler generate such strange code.

11.5 Itanium

Although almost failed, Intel Itanium (IA64) is a very interesting architecture.

While OOE CPUs decides how to rearrange their instructions and execute them in parallel, EPIC\(^2\) was an attempt to shift these decisions to the compiler: to let it group the instructions at the compile stage.

This resulted in notoriously complex compilers.

Here is one sample of IA64 code: simple cryptographic algorithm from the Linux kernel:

Listing 11.3: Linux kernel 3.2.0.4

```c
#define TEA_ROUNDS 32
#define TEA_DELTA 0x9e3779b9

static void tea_encrypt(struct crypto_tfm *tfm, u8 *dst, const u8 *src) {
    u32 y, z, n, sum = 0;
    u32 k0, k1, k2, k3;
    struct tea_ctx *ctx = crypto_tfm_ctx(tfm);
    const __le32 *in = (const __le32 *)src;
    __le32 *out = (__le32 *)dst;
    y = le32_to_cpu(in[0]);
    z = le32_to_cpu(in[1]);
    k0 = ctx->KEY[0];
    k1 = ctx->KEY[1];
    k2 = ctx->KEY[2];
    k3 = ctx->KEY[3];
    n = TEA_ROUNDS;
    while (n-- > 0) {
        sum += TEA_DELTA;
        y += (((z << 4) + k0) ^ (z + sum) ^ ((z >> 5) + k1);
        z += (((y << 4) + k2) ^ (y + sum) ^ ((y >> 5) + k3);
    }
    out[0] = cpu_to_le32(y);
    out[1] = cpu_to_le32(z);
}
```

Here is how it was compiled:

\(^2\)Explicitly Parallel Instruction Computing

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
First of all, all IA64 instructions are grouped into 3-instruction bundles.

Each bundle has a size of 16 bytes (128 bits) and consists of template code (5 bits) + 3 instructions (41 bits for each).

IDA shows the bundles as 6+6+4 bytes—you can easily spot the pattern.

All 3 instructions from each bundle usually executes simultaneously, unless one of instructions has a "stop bit".

Supposedly, Intel and HP engineers gathered statistics on most frequent instruction patterns and decided to bring bundle types (AKA "templates"): a bundle code defines the instruction types in the bundle. There are 12 of them.

For example, the zeroth bundle type is MII, which implies the first instruction is Memory (load or store), the second and third ones are I (integer instructions).

Another example is the bundle of type 0x1d: MFB: the first instruction is Memory (load or store), the second one is Float (FPU instruction), and the third is Branch (branch instruction).

If the compiler cannot pick a suitable instruction for the relevant bundle slot, it may insert a NOP: you
can see here the nop.1 instructions (NOP at the place where the integer instruction might be) or nop.m (a memory instruction might be at this slot).

NOPs are inserted automatically when one uses assembly language manually.

And that is not all. Bundles are also grouped.

Each bundle may have a “stop bit”, so all the consecutive bundles with a terminating bundle which has the “stop bit” can be executed simultaneously.

In practice, Itanium 2 can execute 2 bundles at once, resulting in the execution of 6 instructions at once.

So all instructions inside a bundle and a bundle group cannot interfere with each other (i.e., must not have data hazards).

If they do, the results are to be undefined.

Each stop bit is marked in assembly language as two semicolons (;;) after the instruction.

So, the instructions at [90-ac] may be executed simultaneously: they do not interfere. The next group is [b0-cc].

We also see a stop bit at 10c. The next instruction at 110 has a stop bit too.

This implies that these instructions must be executed isolated from all others (as in CISC).

Indeed: the next instruction at 110 uses the result from the previous one (the value in register r26), so they cannot be executed at the same time.

Apparently, the compiler was not able to find a better way to parallelize the instructions, in other words, to load CPU as much as possible, hence too much stop bits and NOPs.

Manual assembly programming is a tedious job as well: the programmer has to group the instructions manually.

The programmer is still able to add stop bits to each instructions, but this will degrade the performance that Itanium was made for.

An interesting examples of manual IA64 assembly code can be found in the Linux kernel’s sources:

Another very interesting Itanium feature is the speculative execution and the NaT (“not a thing”) bit, somewhat resembling NaN numbers: MSDN.

11.6 8086 memory model

When dealing with 16-bit programs for MS-DOS or Win16 (8.5.3 on page 832 or 3.31.5 on page 654), we can see that the pointers consist of two 16-bit values. What do they mean? Oh yes, that is another weird MS-DOS and 8086 artifact.

8086/8088 was a 16-bit CPU, but was able to address 20-bit address in RAM (thus being able to access 1MB of external memory).

The external memory address space was divided between RAM (640KB max), ROM, windows for video memory, EMS cards, etc.

Let's also recall that 8086/8088 was in fact an inheritor of the 8-bit 8080 CPU.

The 8080 has a 16-bit memory space, i.e., it was able to address only 64KB.

And probably because of reason of old software porting5, 8086 can support many 64KB windows simultaneously, placed within the 1MB address space.

This is some kind of a toy-level virtualization.

3Also available as http://yurichev.com/mirrors/RE/itanium.pdf
4Also available as http://phrack.org/issues/57/5.html
5The author is not 100% sure here
All 8086 registers are 16-bit, so to address more, special segment registers (CS, DS, ES, SS) were introduced.

Each 20-bit pointer is calculated using the values from a segment register and an address register pair (e.g. DS:BX) as follows:

\[
\text{real address} = (\text{segment register} \ll 4) + \text{address register}
\]

For example, the graphics (EGA\(^6\), VGA\(^7\)) video RAM window on old IBM PC-compatibles has a size of 64KB. To access it, a value of 0xA000 has to be stored in one of the segment registers, e.g. into DS.

Then DS:0 will address the first byte of video RAM and DS:0xFFFF — the last byte of RAM.

The real address on the 20-bit address bus, however, will range from 0xA0000 to 0xAFFFF.

The program may contain hard-coded addresses like 0x1234, but the OS may need to load the program at arbitrary addresses, so it recalculates the segment register values in a way that the program does not have to care where it’s placed in the RAM.

So, any pointer in the old MS-DOS environment in fact consisted of the segment address and the address inside segment, i.e., two 16-bit values. 20-bit was enough for that, but we needed to recalculate the addresses very often: passing more information on the stack seemed a better space/convenience balance.

By the way, because of all this it was not possible to allocate a memory block larger than 64KB.

The segment registers were reused at 80286 as selectors, serving a different function.

When the 80386 CPU and computers with bigger RAM were introduced, MS-DOS was still popular, so the DOS extenders emerged: these were in fact a step toward a “serious” OS, switching the CPU in protected mode and providing much better memory APIs for the programs which still needed to run under MS-DOS. Widely popular examples include DOS/4GW (the DOOM video game was compiled for it), Phar Lap, PMODE.

By the way, the same way of addressing memory was used in the 16-bit line of Windows 3.x, before Win32.

### 11.7 Basic blocks reordering

#### 11.7.1 Profile-guided optimization

This optimization method can move some basic blocks to another section of the executable binary file. Obviously, there are parts of a function which are executed more frequently (e.g., loop bodies) and less often (e.g., error reporting code, exception handlers).

The compiler adds instrumentation code into the executable, then the developer runs it with a lot of tests to collect statistics.

Then the compiler, with the help of the statistics gathered, prepares final the executable file with all infrequently executed code moved into another section.

As a result, all frequently executed function code is compacted, and that is very important for execution speed and cache usage.

An example from Oracle RDBMS code, which was compiled with Intel C++:

```plaintext
Listing 11.5: orageneric11.dll (win32)

| public _skgfsync
| _skgfsync proc near |
| ; address 0x6030D86A |
| db 66h |
| nop |
| push ebp |
| mov ebp, esp |
| mov edx, [ebp+0Ch] |
| test edx, edx |

\(^6\)Enhanced Graphics Adapter

\(^7\)Video Graphics Array
```

(For statistics collecting purposes) if you've read this far, please click [here](#). Thanks!
The distance of addresses between these two code fragments is almost 9 MB.

All infrequently executed code was placed at the end of the code section of the DLL file, among all function parts.

This part of the function was marked by the Intel C++ compiler with the VInfreq prefix.

Here we see that a part of the function that writes to a log file (presumably in case of error or warning or something like that) which was probably not executed very often when Oracle’s developers gathered statistics (if it was executed at all).

The writing to log basic block eventually returns the control flow to the “hot” part of the function.

Another “infrequent” part is the basic block returning error code 27050.

In Linux ELF files, all infrequently executed code is moved by Intel C++ into the separate text.unlikely section, leaving all “hot” code in the text.hot section.

From a reverse engineer’s perspective, this information may help to split the function into its core and error handling parts.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
11.8 My experience with Hex-Rays 2.2.0

11.8.1 Bugs

There are couple of bugs.

First of all, Hex-Rays is getting lost when FPU instructions are interleaved (by compiler codegenerator) with others.

For example, this:

```
f    proc    near
    lea    eax, [esp+4]
    fild   dword ptr [eax]
    lea    eax, [esp+8]
    fild   dword ptr [eax]
    fabs   fcompp
    fnstsw  ax
    test   ah, 1
    jz     l01
    mov    eax, 1
    retn
l01:
    mov    eax, 2
    retn
f    endp
```

...will be correctly decompiled to:

```
signed int __cdecl f(signed int a1, signed int a2)
{
    signed int result; // eax@2
    if ( fabs((double)a2) >= (double)a1 )
        result = 2;
    else
        result = 1;
    return result;
}
```

But let's comment one of the instructions at the end:

```
...  ;mov eax, 2
l01:
    retn
...
```

...we getting an obvious bug:

```
void __cdecl f(char a1, char a2)
{
    fabs((double)a2);
}
```

This is another bug:

```
extrn f1:dword
extrn f2:dword
f    proc    near
    fld    dword ptr [esp+4]
    fadd   dword ptr [esp+8]
    fst    dword ptr [esp+12]
```

(For statistics collecting purposes) if you've read this far, please click here. Thanks!
const_100 dd 42C80000h ; 100.0

Result:

int __cdecl f(float a1, float a2, float a3, float a4)
{
    double v5; // st7@1
    char v6; // c0@1
    int result; // eax@2

    v5 = a4;
    if ( v6 )
        result = f2(v5);
    else
        result = f1(v5);
    return result;
}

v6 variable has char type and if you'll try to compile this code, compiler will warn you about variable usage before assignment.
Another bug: FPATAN instruction is correctly decompiled into \texttt{atan2()}, but arguments are swapped.

11.8.2 Odd peculiarities

Hex-Rays too often promotes 32-bit int to 64-bit one. Here is example:

Result:

(For statistics collecting purposes) if you've read this far, please click \texttt{here}. Thanks!
```c
int __cdecl f(int a1, int a2)
{
    __int64 v2; // rax@1
    v2 = abs(a1) - a2;
    return (HIDWORD(v2) ^ v2) - HIDWORD(v2);
}

Perhaps, this is result of CDQ instruction? I'm not sure. Anyway, whenever you see __int64 type in 32-bit code, pay attention.

This is also weird:
```
Many of these peculiarities can be solved by manual reordering of instructions, recompiling assembly code, and then feeding it to Hex-Rays again.

### 11.8.3 Silence

```assembly
extrn some_func:dword

f proc near
    mov ecx, [esp+4]
    mov eax, [esp+8]
    push eax
    call some_func
    add esp, 4
    ; use ECX
    mov eax, ecx
    retn

f endp
```

Result:

```c
int __cdecl f(int a1, int a2)
{
    int v2; // ecx@1
    some_func(a2);
    return v2;
}
```

v2 variable (from ECX) is lost …Yes, this code is incorrect (ECX value doesn’t saved during call to another function), but it would be good for Hex-Rays to give a warning.

Another one:

```assembly
extrn some_func:dword

f proc near
    call some_func
    jnz l01
    mov eax, 1
    retn

l01:
    mov eax, 2
    retn

f endp
```

Result:

```c
signed int f()
{
    char v0; // zf@1
    signed int result; // eax@2
    some_func();
    if (v0)
        result = 1;
    else
        result = 2;
    return result;
}
```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Again, warning would be great.

Anyway, whenever you see variable of *char* type, or variable which is used without initialization, this is clear sign that something went wrong and needs manual intervention.

### 11.8.4 Comma

Comma in C/C++ has a bad fame, because it can lead to a confusing code.

Quick quiz, what does this C/C++ function return?

```c
int f()
{
    return 1, 2;
}
```

It’s 2: when compiler encounters comma-expression, it generates code which executes all sub-expressions, and *returns* value of the last sub-expression.

I’ve seen something like that in production code:

```c
if (cond)
    return global_var=123, 456; // 456 is returned
else
    return global_var=789, 321; // 321 is returned
```

Apparently, programmer wanted to make code slightly shorter without additional curly brackets. In other words, comma allows to pack couple of expressions into one, without forming statement/code block inside of curly brackets.

Comma in C/C++ is close to begin in Scheme/Racket: [https://docs.racket-lang.org/guide/begin.html](https://docs.racket-lang.org/guide/begin.html).

Perhaps, the only widely accepted usage of comma is in *for()* statements:

```c
char *s="hello, world";
for(int i=0; *s; s++, i++)
    // i = string length
```

Both *s++* and *i++* are executed at each loop iteration.

Read more: [https://stackoverflow.com/q/52550](https://stackoverflow.com/q/52550).

I’m writing all this because Hex-Rays produces (at least in my case) code which is rich with both commas and short-circuit expressions. For example, this is real output from Hex-Rays:

```c
if ( (a >= b) || (c = a, (d[a] - e) >> 2 > f) )
{
    ...
```

This is correct, it compiles and works, and let god help you to understand it. Here is it rewritten:

```c
if (cond1 || (comma_expr, cond2))
{
    ...
```

Short-circuit is effective here: first *cond1* is checked, if it’s true, *if()* body is executed, the rest of *if()* expression is ignored completely. If *cond1* is false, *comma_expr* is executed (in the previous example, *a* gets copied to *c*), then *cond2* is checked. If *cond2* is true, *if()* body gets executed, or not. In other words, *if()* body gets executed if *cond1* is true or *cond2* is true, but if the latter is true, *comma_expr* is also executed.

Now you can see why comma is so notorious.

**A word about short-circuit.** A common beginner’s misconception is that sub-conditions are checked in some unspecified order, which is not true. In *a | b | c* expression, *a, b* and *c* gets evaluated in unspecified order, so that is why || has also been added to C/C++, to apply short-circuit explicitly.

---

(For statistics collecting purposes) if you’ve read this far, please click [here](https://example.com). Thanks!
### 11.8.5 Data types

Data types is a problem for decompilers.

Hex-Rays can be blind to arrays in local stack, if they weren’t set correctly before decompilation. Same story about global arrays.

Another problem is too big functions, where a single slot in local stack can be used by several variables across function’s execution. It’s not a rare case when a slot is used for `int`-variable, then for pointer, then for `float`-variable. Hex-Rays correctly decompiles it: it creates a variable with some type, then cast it to another type in various parts of functions. This problem has been solved by me by manual splitting big function into several smaller. Just make local variables as global ones, etc, etc. And don’t forget about tests.

### 11.8.6 Long and messed expressions

Sometimes, during rewriting, you can end up with long and hard to understand expressions in `if()` constructs, like:

```c
if ((!(v38 && v30 <= 5 && v27 != -1)) && (!(v38 && v30 <= 5) && v27 != -1) || (v24 >= 5 || v26)) && v25
{
...
}
```

Wolfram Mathematica can minimize some of them, using `BooleanMinimize[]` function:

```plaintext
In[1]:= BooleanMinimize[!(v38 && v30 <= 5 && v27 != -1)] && !(v38 && v30 <= 5) && v27 != -1 && v30 <= 5
```

```plaintext
Out[1]:= v38 && v25 == 0 && v27 == -1 && v30 <= 5
```

There is even better way, to find common subexpressions:

```plaintext
In[2]:= Experimental`OptimizeExpression[!(v38 && v30 <= 5 && v27 != -1)] && !(v38 && v30 <= 5) && v27 != -1 || (v24 >= 5 || v26) && v25
```

```plaintext
Out[2]= Experimental`OptimizedExpression[
  Block[{Compile`$1, Compile`$2}, Compile`$1 = v30 <= 5;
  Compile`$2 = v27 != -1; !(v38 && Compile`$1 && Compile`$2) &&
  ![c](v38 && Compile`$1 && Compile`$2) || v24 >= 5 || v26 && v25]]
```

Mathematica has added two new variables: `Compile`$1` and `Compile`$2`, values of which are to be used several times in expression. So we can add two additional variables.

### 11.8.7 My plan

- Split big functions (and don’t forget about tests). Sometimes it’s very helpful to form new functions out of big loop bodies.
- Check/set data type of variables, arrays, etc.
- If you see odd result, *dangling* variable (which used before initialization), try to swap instructions manually, recompile it and feed to Hex-Rays again.

### 11.8.8 Summary

Nevertheless, quality of Hex-Rays 2.2.0 is very, very good. It makes life way easier.
Chapter 12

Books/blogs worth reading

12.1 Books and other materials

12.1.1 Reverse Engineering

Also, Kris Kaspersky’s books.

12.1.2 Windows

- Mark Russinovich, *Microsoft Windows Internals*
- Peter Ferrie – The “Ultimate” Anti-Debugging Reference
  
Blogs:

- Microsoft: Raymond Chen
- nynaeve.net

12.1.3 C/C++

- C++11 standard
- Marshall Cline, *C++ FAQ*
- Dennis Yurichev, *C/C++ programming language notes*

12.1.4  x86 / x86-64

- Intel manuals
- AMD manuals

Somewhat outdated, but still interesting to read:

Michael Abrash, *Graphics Programming Black Book*, 1997 (he is known for his work on low-level optimization for such projects as Windows NT 3.1 and id Quake).

12.1.5  ARM

- ARM manuals
- [*ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile*, (2013)]

12.1.6 Assembly language

Richard Blum — Professional Assembly Language.

12.1.7 Java

12.1.8 UNIX

11 Also available as http://www.agner.org/optimize/calling_conventions.pdf
12 Also available as https://github.com/jagregory/abrash-black-book
15 Also available as http://go.yurichev.com/17273
16 Also available as https://docs.oracle.com/javase/specs/jvms/se7/jvms7.pdf; http://docs.oracle.com/javase/specs/jvms/se7/html/
12.1.9 Programming in general

- Henry S. Warren, *Hacker’s Delight*, (2002). Some people say tricks and hacks from the book are not relevant today because they were good only for RISC CPUs, where branching instructions are expensive. Nevertheless, these can help immensely to understand boolean algebra and what all the mathematics near it.
- (For hard-core geeks with computer science and mathematical background) Donald E. Knuth, *The Art of Computer Programming*. Some people arguing, if it worth for an average programmer to try hard to read these quite hard fundamental books. I would say, it's worth just to skim them, to learn what CS1\(^{17}\) consists of.

12.1.10 Cryptography

- (Free) lvh, *Crypto 101*\(^{18}\)
- (Free) Dan Boneh, Victor Shoup, *A Graduate Course in Applied Cryptography*\(^{19}\).

Chapter 13

Communities

There are two excellent RE\textsuperscript{1}-related subreddits on reddit.com: reddit.com/r/ReverseEngineering/ and reddit.com/r/remath (on the topics for the intersection of RE and mathematics).

There is also a RE part of the Stack Exchange website: reverseengineering.stackexchange.com.

On IRC there’s a ##re channel on FreeNode\textsuperscript{2}.

\textsuperscript{1}Reverse Engineering

\textsuperscript{2}freenode.net
Afterword
13.1 Questions?

Do not hesitate to mail any questions to the author: <dennis@yurichev.com>. Do you have any suggestion on new content for the book? Please do not hesitate to send any corrections (including grammar (you see how horrible my English is?!)), etc.

The author is working on the book a lot, so the page and listing numbers, etc., are changing very rapidly. Please do not refer to page and listing numbers in your emails to me. There is a much simpler method: make a screenshot of the page, in a graphics editor underline the place where you see the error, and send it to the author. He’ll fix it much faster. And if you familiar with git and \LaTeX{} you can fix the error right in the source code:

GitHub.

Do not worry to bother me while writing me about any petty mistakes you found, even if you are not very confident. I’m writing for beginners, after all, so beginners’ opinions and comments are crucial for my job.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
Appendix
.1 x86

.1.1 Terminology

Common for 16-bit (8086/80286), 32-bit (80386, etc.), 64-bit.

**byte** 8-bit. The DB assembly directive is used for defining variables and arrays of bytes. Bytes are passed in the 8-bit part of registers: AL/BL/CL/DL/AH/BH/CH/DH/SIL/DIL/R*L.

**word** 16-bit. DW assembly directive —“”—. Words are passed in the 16-bit part of the registers: AX/BX/CX/DX/SI/DI/R*W.

**double word** (“dword”) 32-bit. DD assembly directive —”—. Double words are passed in registers (x86) or in the 32-bit part of registers (x64). In 16-bit code, double words are passed in 16-bit register pairs.

**quad word** (“qword”) 64-bit. DQ assembly directive —”—. In 32-bit environment, quad words are passed in 32-bit register pairs.

**tbyte** (10 bytes) 80-bit or 10 bytes (used for IEEE 754 FPU registers).

**paragraph** (16 bytes)—term was popular in MS-DOS environment.

Data types of the same width (BYTE, WORD, DWORD) are also the same in Windows API.

.1.2 General purpose registers

It is possible to access many registers by byte or 16-bit word parts. .

It is all inheritance from older Intel CPUs (up to the 8-bit 8080) still supported for backward compatibility. Older 8-bit CPUs (8080) had 16-bit registers divided by two.

Programs written for 8080 could access the low byte part of 16-bit registers, high byte part or the whole 16-bit register.

Perhaps, this feature was left in 8086 as a helper for easier porting.

This feature is usually not present in RISC CPUs.

Registers prefixed with R- appeared in x86-64, and those prefixed with E —in 80386.

Thus, R-registers are 64-bit, and E-registers—32-bit.

8 more GPR’s were added in x86-86: R8-R15. .

N.B.: In the Intel manuals the byte parts of these registers are prefixed by L, e.g.: R8L, but IDA names these registers by adding the B suffix, e.g.: R8B.

**RAX/EAX/AX/AL**

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAX*x64</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EAX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AH AL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AKA accumulator. The result of a function is usually returned via this register.

**RBX/EBX/BX/BL**

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBX*x64</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EBX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BX</td>
<td></td>
<td></td>
<td></td>
<td></td>

</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
### RCX/ECX/CX/CL

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCX&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ECX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CH</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AKA counter**: in this role it is used in REP prefixed instructions and also in shift instructions (SHL/SHR/RxL/RxR).

### RDX/EDX/DX/DL

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDX&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EDX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DX</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DH</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### RSI/ESI/SI/SIL

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSI&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ESI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SIL&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AKA** “source index”. Used as source in the instructions REP MOVsx, REP CMPSx.

### RDI/EDI/DI/DIL

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDI&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EDI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DIL&lt;sub&gt;x64&lt;/sub&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AKA** “destination index”. Used as a pointer to the destination in the instructions REP MOVsx, REP STOSx.

### R8/R8D/R8W/R8L

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>R8</td>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R8W</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>R8L</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### R9/R9D/R9W/R9L

<table>
<thead>
<tr>
<th>Byte number:</th>
<th>7th</th>
<th>6th</th>
<th>5th</th>
<th>4th</th>
<th>3rd</th>
<th>2nd</th>
<th>1st</th>
<th>0th</th>
</tr>
</thead>
<tbody>
<tr>
<td>R9</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
AKA stack pointer. Usually points to the current stack except in those cases when it is not yet initialized.

**RBP/EBP/BP/BPL**

AKA frame pointer. Usually used for local variables and accessing the arguments of the function. More about it: (1.12.1 on page 67).

**RIP/EIP/IP**

AKA “instruction pointer”\(^3\). Usually always points to the instruction to be executed right now. Cannot be modified, however, it is possible to do this (which is equivalent):

\[
\begin{align*}
\text{MOV EAX, ...} \\
\text{JMP EAX}
\end{align*}
\]

Or:

\[
\begin{align*}
\text{PUSH value} \\
\text{RET}
\end{align*}
\]

**CS/DS/ES/SS/FS/GS**

16-bit registers containing code selector (CS), data selector (DS), stack selector (SS).

FS in win32 points to TLS, GS took this role in Linux. It is made so for faster access to the TLS and other structures like the TIB.

In the past, these registers were used as segment registers (11.6 on page 976).

**Flags register**

AKA EFLAGS.

\(^3\)Sometimes also called “program counter”
<table>

<td>ID (Identification)</td>
<td></td>
</tr>
</tbody>
</table>

All the rest flags are reserved.

### 1.3 FPU registers

8 80-bit registers working as a stack: ST(0)-ST(7). N.B.: IDA calls ST(0) as just ST. Numbers are stored in the IEEE 754 format.

**long double** value format:

```
  79  78  64  63  62  0
  \   \   \   \   \   \   \   \   \
S exponent I mantissa or fraction
```

( S — sign, I — integer part )

**Control Word**

Register controlling the behavior of the FPU.

</tbody>
</table>
| 8, 9 | PC (Precision Control) | 00 — 24 bits (REAL4)  
|      |                        | 10 — 53 bits (REAL8)  
|      |                        | 11 — 64 bits (REAL10) |
| 10, 11 | RC (Rounding Control) | 00 — (by default) round to nearest  
|        |                        | 01 — round toward −∞  
|        |                        | 10 — round toward +∞  
|        |                        | 11 — round toward 0 |
| 12   | IC (Infinity Control) | 0 — (by default) treat +∞ and −∞ as unsigned  
|      |                        | 1 — respect both +∞ and −∞ |

The PM, UM, OM, ZM, DM, IM flags define if to generate exception in the case of a corresponding error.

**Status Word**

Read-only register.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Abbreviation (meaning)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>B (Busy)</td>
<td>Is FPU do something (1) or results are ready (0)</td>
</tr>
<tr>
<td>14</td>
<td>C3</td>
<td></td>
</tr>
<tr>
<td>13, 12, 11</td>
<td>TOP</td>
<td>points to the currently zeroth register</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>1</td>
<td>D (Denormalized)</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>I (Invalid operation)</td>
<td></td>
</tr>
</tbody>
</table>

The SF, P, U, O, Z, D, I bits signal about exceptions.

About the C3, C2, C1, C0 you can read more here: ([1.25.7 on page 234](#)).

N.B.: When ST(x) is used, the FPU adds x to TOP (by modulo 8) and that is how it gets the internal register’s number.

**Tag Word**

The register has current information about the usage of numbers registers.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Abbreviation (meaning)</th>
</tr>
</thead>
<tbody>
<tr>
<td>15, 14</td>
<td>tag(7)</td>
</tr>
<tr>
<td>13, 12</td>
<td>tag(6)</td>
</tr>
<tr>
<td>11, 10</td>
<td>tag(5)</td>
</tr>
<tr>
<td>9, 8</td>
<td>tag(4)</td>
</tr>
<tr>
<td>7, 6</td>
<td>tag(3)</td>
</tr>
<tr>
<td>5, 4</td>
<td>tag(2)</td>
</tr>
<tr>
<td>3, 2</td>
<td>tag(1)</td>
</tr>
<tr>
<td>1, 0</td>
<td>tag(0)</td>
</tr>
</tbody>
</table>

Each tag contains information about a physical FPU register (R(x)), not logical (ST(x)).

For each tag:
• 00 — The register contains a non-zero value
• 01 — The register contains 0
• 10 — The register contains a special value (NAN⁴, ∞, or denormal)
• 11 — The register is empty

### 1.4 SIMD registers

**MMX registers**

8 64-bit registers: MM0..MM7.

**SSE and AVX registers**

SSE: 8 128-bit registers: XMM0..XMM7. In the x86-64 8 more registers were added: XMM8..XMM15.

AVX is the extension of all these registers to 256 bits.

### 1.5 Debugging registers

Used for hardware breakpoints control.

- DR0 — address of breakpoint #1
- DR1 — address of breakpoint #2
- DR2 — address of breakpoint #3
- DR3 — address of breakpoint #4
- DR6 — a cause of break is reflected here
- DR7 — breakpoint types are set here

**DR6**

<table>
<thead>
<tr>
<th>Bit (mask)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (1)</td>
<td>B0 — breakpoint #1 has been triggered</td>
</tr>
<tr>
<td>1 (2)</td>
<td>B1 — breakpoint #2 has been triggered</td>
</tr>
<tr>
<td>2 (4)</td>
<td>B2 — breakpoint #3 has been triggered</td>
</tr>
<tr>
<td>3 (8)</td>
<td>B3 — breakpoint #4 has been triggered</td>
</tr>
<tr>
<td>13 (0x2000)</td>
<td>BD — modification attempt of one of the DRx registers. may be raised if GD is enabled</td>
</tr>
<tr>
<td>14 (0x4000)</td>
<td>BS — single step breakpoint (TF flag has been set in EFLAGS). Highest priority. Other bits may also be set.</td>
</tr>
<tr>
<td>15 (0x8000)</td>
<td>BT (task switch flag)</td>
</tr>
</tbody>
</table>

N.B. A single step breakpoint is a breakpoint which occurs after each instruction. It can be enabled by setting TF in EFLAGS (.1.2 on page 995).

**DR7**

Breakpoint types are set here.

⁴Not a Number

<td>breakpoint #4: R/W — type</td>
</tr>
<tr>
<td>30,31 (0xC00000000)</td>
<td>breakpoint #4: LEN — length</td>
</tr>
</tbody>
</table>

The breakpoint type is to be set as follows (R/W):

- 00 — instruction execution
- 01 — data writes
- 10 — I/O reads or writes (not available in user-mode)
- 11 — on data reads or writes

N.B.: breakpoint type for data reads is absent, indeed.

Breakpoint length is to be set as follows (LEN):

- 00 — one-byte
- 01 — two-byte
- 10 — undefined for 32-bit mode, eight-byte in 64-bit mode
- 11 — four-byte

.1.6 Instructions

Instructions marked as (M) are not usually generated by the compiler: if you see one of them, it is probably a hand-written piece of assembly code, or a compiler intrinsic (11.3 on page 972).

Only the most frequently used instructions are listed here. You can read 12.1.4 on page 986 for a full documentation.

Do you have to know all instruction’s opcodes by heart? No, only those which are used for code patching (11.1.2 on page 971). All the rest of the opcodes don’t need to be memorized.

Prefixes

**LOCK** forces CPU to make exclusive access to the RAM in multiprocessor environment. For the sake of simplification, it can be said that when an instruction with this prefix is executed, all other CPUs in a multiprocessor system are stopped. Most often it is used for critical sections, semaphores, mutexes. Commonly used with ADD, AND, BTR, BTS, CMPXCHG, OR, XADD, XOR. You can read more about critical sections here (6.5.4 on page 787).

**REP** is used with the MOVSx and STOSx instructions: execute the instruction in a loop, the counter is located in the CX/ECX/RCX register. For a detailed description, read more about the MOVSx (.1.6 on page 1002) and STOSx (.1.6 on page 1003) instructions.

The instructions prefixed by REP are sensitive to the DF flag, which is used to set the direction.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
REPE/REPNE (AKA REPZ/REPNZ) used with CMPSx and SCASx instructions: execute the last instruction in a loop, the count is set in the CX/ECX/RCX register. It terminates prematurely if ZF is 0 (REPE) or if ZF is 1 (REPNNE).

For a detailed description, you can read more about the CMPSx (.1.6 on page 1005) and SCASx (.1.6 on page 1003) instructions.

Instructions prefixed by REPE/REPNE are sensitive to the DF flag, which is used to set the direction.

Most frequently used instructions

These can be memorized in the first place.

ADC (add with carry) add values, increment the result if the CF flag is set. ADC is often used for the addition of large values, for example, to add two 64-bit values in a 32-bit environment using two ADD and ADC instructions. For example:

```
; work with 64-bit values: add val1 to val2.
; .lo means lowest 32 bits, .hi means highest.
ADD val1.lo, val2.lo
ADC val1.hi, val2.hi ; use CF that was set or cleared at the previous instruction
```

One more example: 1.34 on page 398.

ADD add two values

AND logical “and”

CALL call another function:

```
PUSH address_after_CALL_instruction; JMP label
```

CMP compare values and set flags, the same as SUB but without writing the result

DEC decrement. Unlike other arithmetic instructions, DEC doesn’t modify CF flag.

IMUL signed multiply IMUL often used instead of MUL, read more about it: 2.2.1 on page 459.

INC increment. Unlike other arithmetic instructions, INC doesn’t modify CF flag.

JCXZ, JECXZ, JRCXZ (M) jump if CX/ECX/RCX=0

JMP jump to another address. The opcode has a jump offset.

Jcc (where cc — condition code)

A lot of these instructions have synonyms (denoted with AKA), this was done for convenience. Synonymous instructions are translated into the same opcode. The opcode has a jump offset.

<table>

</table>

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
JNE  AKA JNZ: jump if not equal or not zero: ZF=0
JNGE jump if not greater or equal (signed): SF≠OF
JNG jump if not greater (signed): ZF=1 or SF≠OF
JNLE jump if not lesser (signed): ZF=0 and SF=OF
JNLE jump if not lesser (signed): SF=OF
JNS jump if SF flag is cleared
JNZ  AKA JNE: jump if not equal or not zero: ZF=0
JO jump if overflow: OF=1
JPO jump if PF flag is cleared (Jump Parity Odd)
JP  AKA JPE: jump if PF flag is set
JS jump if SF flag is set
JZ  AKA JE: jump if equal or zero: ZF=1

LAHF copy some flag bits to AH:

<table>
<thead>
<tr>
<th>SF</th>
<th>ZF</th>
<th>AF</th>
<th>PF</th>
<th>CF</th>
</tr>
</thead>
</table>

This instruction is often used in FPU-related code.

LEAVE equivalent of the MOV ESP, EBP and POP EBP instruction pair — in other words, this instruction sets the stack pointer (ESP) back and restores the EBP register to its initial state.

LEA (Load Effective Address) form an address

This instruction was intended not for summing values and multiplication but for forming an address, e.g., for calculating the address of an array element by adding the array address, element index, with multiplication of element size.

So, the difference between MOV and LEA is that MOV forms a memory address and loads a value from memory or stores it there, but LEA just forms an address.

But nevertheless, it is can be used for any other calculations.

LEA is convenient because the computations performed by it does not alter CPU flags. This may be very important for OOE processors (to create less data dependencies).

Aside from this, starting at least at Pentium, LEA instruction is executed in 1 cycle.

```c
int f(int a, int b)
{
    return a*8+b;
};
```

Listing 1: Optimizing MSVC 2010

```
_a$ = 8 ; size = 4
_b$ = 12; size = 4
_f PROC
    mov    eax, DWORD PTR _b$[esp-4]
    mov    ecx, DWORD PTR _a$[esp-4]
    lea    eax, DWORD PTR [eax+ecx*8]
    ret    0
_f ENDP

Intel C++ uses LEA even more:

```c
int f1(int a)
{
    return a*13;
};
```

5See also: wikipedia

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
These two instructions performs faster than one IMUL.

**MOVSB/MOVSW/MOVSD/MOVSDQ** copy byte/ 16-bit word/ 32-bit word/ 64-bit word from the address which is in SI/ESI/RSI into the address which is in DI/EDI/RDI.

Together with the REP prefix, it is to be repeated in a loop, the count is to be stored in the CX/ECX/RCX register: it works like memcpy() in C. If the block size is known to the compiler in the compile stage, memcpy() is often inlined into a short code fragment using REP MOVXSx, sometimes even as several instructions.

The memcpy(EDI, ESI, 15) equivalent is:

```assembly
; copy 15 bytes from ESI to EDI
CLD
; set direction to forward
MOV ECX, 3
REP MOVSD ; copy 12 bytes
MOVSW ; copy 2 more bytes
MOVSX ; copy remaining byte
```

(Supposedly, it works faster than copying 15 bytes using just one REP MOVSB).

**MOVSX** load with sign extension see also: (1.23.1 on page 204)

**MOVZX** load and clear all other bitsi see also: (1.23.1 on page 204)

**MOV** load value. this instruction name is misnomer, resulting in some confusion (data is not moved but copied), in other architectures the same instructions is usually named “LOAD” and/or “STORE” or something like that.

One important thing: if you set the low 16-bit part of a 32-bit register in 32-bit mode, the high 16 bits remains as they were. But if you modify the low 32-bit part of the register in 64-bit mode, the high 32 bits of the register will be cleared.

Supposedly, it was done to simplify porting code to x86-64.

**MUL** unsigned multiply. IMUL often used instead of MUL, read more about it: 2.2.1 on page 459.

**NEG** negation: $op = \neg op$. Same as NOT op / ADD op, 1.

**NOP** Its opcode is 0x90, it is in fact the XCHG EAX,EAX idle instruction. This implies that x86 does not have a dedicated NOP instruction (as in many RISC). This book has at least one listing where GDB shows NOP as 16-bit XCHG instruction: 1.11.1 on page 48.

More examples of such operations: (.1.7 on page 1011).

**NOP** may be generated by the compiler for aligning labels on a 16-byte boundary. Another very popular usage of NOP is to replace manually (patch) some instruction like a conditional jump to NOP in order to disable its execution.

**NOT** $op1: \neg op1$. logical inversion Important feature—the instruction doesn't change flags.

**OR** logical “or”

**POP** get a value from the stack: value=SS:[ESP]; ESP=ESP+4 (or 8)

**PUSH** push a value into the stack: ESP=ESP-4 (or 8); SS:[ESP]=value

**RET** return from subroutine: POP tmp; JMP tmp.

In fact, RET is an assembly language macro, in Windows and *NIX environment it is translated into RETN (“return near”) or, in MS-DOS times, where the memory was addressed differently (11.6 on page 976), into RETF (“return far”).

RET can have an operand. Then it works like this: POP tmp; ADD ESP op1; JMP tmp. RET with an operand usually ends functions in the stdcall calling convention, see also: 6.1.2 on page 733.

**SAHF** copy bits from AH to CPU flags:

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
This instruction is often used in FPU-related code.

**SBB** (*subtraction with borrow*) subtract values, decrement the result if the CF flag is set. SBB is often used for subtraction of large values, for example, to subtract two 64-bit values in 32-bit environment using two SUB and SBB instructions. For example:

```
; work with 64-bit values: subtract val2 from val1.
; .lo means lowest 32 bits, .hi means highest.
SUB val1.lo, val2.lo
SBB val1.hi, val2.hi ; use CF that was set or cleared at the previous instruction
```

One more example: 1.34 on page 398.

**SCASB/SCASW/SCASD/SCASQ** (M) compare byte/ 16-bit word/ 32-bit word/ 64-bit word that’s stored in AX/EAX/RAX with a variable whose address is in DI/EDI/RDI. Set flags as CMP does.

This instruction is often used with the REPNE prefix: continue to scan the buffer until a special value stored in AX/EAX/RAX is found. Hence “NE” in REPNE: continue to scan while the compared values are not equal and stop when equal.

It is often used like the strlen() C standard function, to determine an ASCII string’s length:

Example:

```
lea   edi, string
mov   ecx, 0FFFFFFFFh ; scan 2^32−1 bytes, i.e., almost infinitely
xor   eax, eax ; 0 is the terminator
repne scasb
add   edi, 0FFFFFFFFh ; correct it

; now EDI points to the last character of the ASCII string.

; lets determine string length
; current ECX = -1-strlen
not   ecx
dec   ecx

; now ECX contain string length
```

If we use a different AX/EAX/RAX value, the function acts like the memchr() standard C function, i.e., it finds a specific byte.

**SHL** shift value left

**SHR** shift value right:

```
    7 6 5 4 3 2 1 0
CF
```

```
    7 6 5 4 3 2 1 0
    0
```

```
    7 6 5 4 3 2 1 0
    0
```

These instructions are frequently used for multiplication and division by 2^n. Another very frequent application is processing bit fields: 1.28 on page 307.

**SHRD** op1, op2, op3: shift value in op2 right by op3 bits, taking bits from op1.

Example: 1.34 on page 398.

**STOSB/STOSW/STOSD/STOSQ** store byte/ 16-bit word/ 32-bit word/ 64-bit word from AX/EAX/RAX into the address which is in DI/EDI/RDI.
Together with the REP prefix, it is to be repeated in a loop, the counter is in the CX/ECX/RCX register: it works like memset() in C. If the block size is known to the compiler on compile stage, memset() is often inlined into a short code fragment using REP MOVSx, sometimes even as several instructions.

memset(EDI, 0xAA, 15) equivalent is:

```assembly
CLD ; set direction to forward
MOV EAX, 0AAAAAAAh
MOV ECX, 3
REP STOSD ; write 12 bytes
STOSW ; write 2 more bytes
STOSB ; write remaining byte
```

(Supposedly, it works faster than storing 15 bytes using just one REP STOSB).

**SUB** subtract values. A frequently occurring pattern is SUB reg, reg, which implies zeroing of reg.

**TEST** same as AND but without saving the result, see also: 1.28 on page 307

**XOR** op1, op2: XOR values. op1 = op1 ⊕ op2. A frequently occurring pattern is XOR reg, reg, which implies zeroing of reg. See also: 2.6 on page 466.

### Less frequently used instructions

**BSF** bit scan forward, see also: 1.36.2 on page 423

**BSR** bit scan reverse

**BSWAP** (byte swap), change value endianness.

**BTC** bit test and complement

**BTR** bit test and reset

**BTS** bit test and set

**BT** bit test

**CBW/CWD/CWDE/CDQ/CDQE** Sign-extend value:

- **CBW** convert byte in AL to word in AX
- **CWD** convert word in AX to doubleword in DX:AX
- **CWDE** convert word in AX to doubleword in EAX
- **CDQ** convert doubleword in EAX to quadword in EDX:EAX
- **CDQE** (x64) convert doubleword in EAX to quadword in RAX

These instructions consider the value’s sign, extending it to high part of the newly constructed value. See also: 1.34.5 on page 407.

Interestingly to know these instructions was initially named as **SEX** (*Sign EXTend*), as Stephen P. Morse (one of Intel 8086 CPU designers) wrote in [Stephen P. Morse, *The 8086 Primer*, (1980)]:

> The process of stretching numbers by extending the sign bit is called sign extension. The 8086 provides instructions (Fig. 3.29) to facilitate the task of sign extension. These instructions were initially named SEX (sign extend) but were later renamed to the more conservative CBW (convert byte to word) and CWD (convert word to double word).

**CLD** clear DF flag.

**CLI** (M) clear IF flag.

**CMC** (M) toggle CF flag

**CMOVcc** conditional MOV: load if the condition is true. The condition codes are the same as in the Jcc instructions (.1.6 on page 1000).

---

6 Exclusive OR

7 Also available as https://archive.org/details/The8086Primer

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
CMPSB/CMPSW/CMPSD/CMPSQ (M) compare byte/ 16-bit word/ 32-bit word/ 64-bit word from the address which is in SI/ESI/RSI with the variable at the address stored in DI/EDI/RDI. Set flags as CMP does.

Together with the REP prefix, it is to be repeated in a loop, the counter is stored in the CX/ECX/RCX register, the process will run until the ZF flag is zero (e.g., until the compared values are equal to each other, hence “E” in REPE).

It works like memcmp() in C.

Example from the Windows NT kernel (WRK v1.2):

```asm
; ULONG
; RtlCompareMemory (;
; IN PVOID Source1,;
; IN PVOID Source2,;
; IN ULONG Length
;)
;
; Routine Description:
;
; This function compares two blocks of memory and returns the number
; of bytes that compared equal.
;
; Arguments:
;
; Source1 (esp+4) - Supplies a pointer to the first block of memory to
; compare.
;
; Source2 (esp+8) - Supplies a pointer to the second block of memory to
; compare.
;
; Length (esp+12) - Supplies the Length, in bytes, of the memory to be
; compared.
;
; Return Value:
;
; The number of bytes that compared equal is returned as the function
; value. If all bytes compared equal, then the length of the original
; block of memory is returned.
;
; --

RcmSource1   equ  [esp+12]
RcmSource2   equ  [esp+16]
RcmLength    equ  [esp+20]

    shr    ecx,2            ; (ecx) = length in dwords
    jz     rcm20            ; no dwords, try bytes
    repe   cmpsd            ; compare dwords
    jnz    rcm40            ; mismatch, go find byte

    ; Compare residual bytes, if any.

```

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
rcm20:  mov     ecx,RcmLength  ; (ecx) = length in bytes
          and    ecx,3          ; (ecx) = length mod 4
          jz     rcm30          ; 0 odd bytes, go do dwords
          repe   cmpsb          ; compare odd bytes
          jnz    rcm50          ; mismatch, go report how far we got

; All bytes in the block match.

rcm30:  mov     eax,RcmLength  ; set number of matching bytes
          pop    edi             ; restore registers
          pop    esi             ;
          stdRET   _RtlCompareMemory;

; When we come to rcm40, esi (and edi) points to the dword after the
; one which caused the mismatch. Back up 1 dword and find the byte.
; Since we know the dword didn't match, we can assume one byte won't.

rcm40:  sub     esi,4          ; back up
          sub     edi,4          ; back up
          mov     ecx,5          ; ensure that ecx doesn't count out
          repe    cmpsb          ; find mismatch byte

; When we come to rcm50, esi points to the byte after the one that
; did not match, which is TWO after the last byte that did match.

rcm50:  dec     esi           ; back up
          sub     esi,RcmSource1 ; compute bytes that matched
          mov     eax,esi         ;
          pop     edi             ; restore registers
          pop     esi             ;
          stdRET   _RtlCompareMemory

stdENDP   _RtlCompareMemory

N.B.: this function uses a 32-bit word comparison (CMPSD) if the block size is a multiple of 4, or
per-byte comparison (CMPSB) otherwise.

CPUID  get information about the CPU's features. see also: (1.30.6 on page 372).

DIV  unsigned division

IDIV  signed division

INT (M): INT x is analogous to PUSHF; CALL dword ptr [x*4] in 16-bit environment. It was widely
used in MS-DOS, functioning as a syscall vector. The registers AX/BX/CX/DX/SI/DI were filled with
the arguments and then the flow jumped to the address in the Interrupt Vector Table (located at the
beginning of the address space). It was popular because INT has a short opcode (2 bytes) and the
program which needs some MS-DOS services is not bother to determine the address of the service's
entry point. The interrupt handler returns the control flow to caller using the IRET instruction.
The most busy MS-DOS interrupt number was 0x21, serving a huge part of its API. See also: [Ralf
Brown Ralf Brown's Interrupt List], for the most comprehensive interrupt lists and other MS-DOS
information.

In the post-MS-DOS era, this instruction was still used as syscall both in Linux and Windows (6.3 on
page 746), but was later replaced by the SYSENTER or SYSCALL instructions.

INT3 (M): this instruction is somewhat close to INT, it has its own 1-byte opcode (0xCC), and is actively
used while debugging. Often, the debuggers just write the 0xCC byte at the address of the breakpoint
to be set, and when an exception is raised, the original byte is restored and the original instruction
at this address is re-executed.
As of Windows NT, an EXCEPTION_BREAKPOINT exception is to be raised when the CPU executes this
instruction. This debugging event may be intercepted and handled by a host debugger, if one is

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
If it is not loaded, Windows offers to run one of the registered system debuggers. If MSVS
is installed, its debugger may be loaded and connected to the process. In order to protect from reverse
engineering, a lot of anti-debugging methods check integrity of the loaded code.

MSVC has compiler intrinsic for the instruction: __debugbreak().

There is also a win32 function in kernel32.dll named DebugBreak(), which also executes INT 3.

IN (M) input data from port. The instruction usually can be seen in OS drivers or in old MS-DOS code, for example (8.5.3 on page 832).

IRET : was used in the MS-DOS environment for returning from an interrupt handler after it was called by the INT instruction. Equivalent to POP tmp; POPF; JMP tmp.

LOOP (M) decrement CX/ECX/RCX, jump if it is still not zero.

LOOP instruction was often used in DOS-code which works with external devices. To add small delay, this was done:

```
MOV CX, nnnn
LABEL: LOOP LABEL
```

Drawback is obvious: length of delay depends on CPU speed.

OUT (M) output data to port. The instruction usually can be seen in OS drivers or in old MS-DOS code, for example (8.5.3 on page 832).

POPA (M) restores values of (R|E)DI, (R|E)SI, (R|E)BP, (R|E)BX, (R|E)DX, (R|E)CX, (R|E)AX registers from the stack.

POPCNT population count. Counts the number of 1 bits in the value.

See: 2.7 on page 469.

POPF restore flags from the stack (AKA EFLAGS register)

PUSHA (M) pushes the values of the (R|E)AX, (R|E)CX, (R|E)DX, (R|E)BX, (R|E)BP, (R|E)SI, (R|E)DI registers to the stack.

PUSHF push flags (AKA EFLAGS register)

RCL (M) rotate left via CF flag:

```
7 6 5 4 3 2 1 0 CF
7 6 5 4 3 2 1 0 CF
```

RCR (M) rotate right via CF flag:

```
7 6 5 4 3 2 1 0 CF
7 6 5 4 3 2 1 0 CF
```

ROL/ROR (M) cyclic shift

ROL: rotate left:

```
7 6 5 4 3 2 1 0 CF
7 6 5 4 3 2 1 0 CF
```

ROR: rotate right:

Despite the fact that almost all CPUs have these instructions, there are no corresponding operations in C/C++, so the compilers of these PLs usually do not generate these instructions.

For the programmer’s convenience, at least MSVC has the pseudofunctions (compiler intrinsics) _rotl() and _rotr()\(^1\), which are translated by the compiler directly to these instructions.

**SAL** Arithmetic shift left, synonymous to SHL

**SAR** Arithmetic shift right

Hence, the sign bit always stays at the place of the MSB.

**SETcc** op: load 1 to operand (byte only) if the condition is true or zero otherwise. The condition codes are the same as in the Jcc instructions (\(^1.6\) on page 1000).

**STC** (M) set CF flag

**STD** (M) set DF flag. This instruction is not generated by compilers and generally rare. For example, it can be found in the ntoskrnl.exe Windows kernel file, in the hand-written memory copy routines.

**STI** (M) set IF flag

**SYSCALL** (AMD) call syscall (\(^6.3\) on page 746)

**SYSENTER** (Intel) call syscall (\(^6.3\) on page 746)

**UD2** (M) undefined instruction, raises exception. Used for testing.

**XCHG** (M) exchange the values in the operands

This instruction is rare: compilers don’t generate it, because starting at Pentium, XCHG with address in memory in operand executes as if it has LOCK prefix ([Michael Abrash, \textit{Graphics Programming Black Book}, 1997 chapter 19]). Perhaps, Intel engineers did so for compatibility with synchronizing primitives. Hence, XCHG starting at Pentium can be slow. On the other hand, XCHG was very popular in assembly language programmers. So if you see XCHG in code, it can be a sign that this piece of code is written manually. However, at least Borland Delphi compiler generates this instruction.

**FPU instructions**

- \(\text{R}\) suffix in the mnemonic usually implies that the operands are reversed, - \(\text{P}\) suffix implies that one element is popped from the stack after the instruction’s execution, - \(\text{PP}\) suffix implies that two elements are popped.
- \(\text{P}\) instructions are often useful when we do not need the value in the FPU stack to be present anymore after the operation.

**FABS** replace value in ST(0) by absolute value in ST(0)

**FADD** op: ST(0)=op+ST(0)

**FADD** ST(0), ST(i): ST(0)=ST(0)+ST(i)

**FADDP** ST(1)=ST(0)+ST(1); pop one element from the stack, i.e., the values in the stack are replaced by their sum

**FCHS** ST(0)=−ST(0)

**FCOM** compare ST(0) with ST(1)

**FCOM** op: compare ST(0) with op

**FCOMP** compare ST(0) with ST(1); pop one element from the stack

\(^1\)MSDN

(For statistics collecting purposes) if you’ve read this far, please click \textit{here}. Thanks!
FCOMPP compare ST(0) with ST(1); pop two elements from the stack

FDIVR op: ST(0)=op/ST(0)
FDIVR ST(i), ST(j): ST(i)=ST(j)/ST(i)
FDIVRP op: ST(0)=op/ST(0); pop one element from the stack
FDIVRP ST(i), ST(j): ST(i)=ST(j)/ST(i); pop one element from the stack
FDIV op: ST(0)=ST(0)/op
FDIV ST(i), ST(j): ST(i)=ST(i)/ST(j)
FDIVP ST(1)=ST(0)/ST(1); pop one element from the stack, i.e., the dividend and divisor values in the stack are replaced by quotient

FILD op: convert integer and push it to the stack.
FIST op: convert ST(0) to integer op
FISTP op: convert ST(0) to integer op; pop one element from the stack
FLD1 push 1 to stack
FLDCW op: load FPU control word (.1.3 on page 996) from 16-bit op.
FLDZ push zero to stack
FLD op: push op to the stack.
FMUL op: ST(0)=ST(0)*op
FMUL ST(i), ST(j): ST(i)=ST(i)*ST(j)
FMULP op: ST(0)=ST(0)*op; pop one element from the stack
FMULP ST(i), ST(j): ST(i)=ST(i)*ST(j); pop one element from the stack
FSINCOS: tmp=ST(0); ST(1)=sin(tmp); ST(0)=cos(tmp)
FSQRT: ST(0) = √ST(0)
FSTCW op: store FPU control word (.1.3 on page 996) into 16-bit op after checking for pending exceptions.
FNSTCW op: store FPU control word (.1.3 on page 996) into 16-bit op.
FSTSW op: store FPU status word (.1.3 on page 997) into 16-bit op after checking for pending exceptions.
FNSTSW op: store FPU status word (.1.3 on page 997) into 16-bit op.
FST op: copy ST(0) to op
FSTP op: copy ST(0) to op; pop one element from the stack
FSUBR op: ST(0)=op-ST(0)
FSUBR ST(0), ST(i): ST(0)=ST(i)-ST(0)
FSUBRP ST(1)=ST(0)-ST(1); pop one element from the stack, i.e., the value in the stack is replaced by the difference
FSUB op: ST(0)=ST(0)-op
FSUB ST(0), ST(i): ST(0)=ST(0)-ST(i)
FSUBP ST(1)=ST(1)-ST(0); pop one element from the stack, i.e., the value in the stack is replaced by the difference
FUCOM ST(i): compare ST(0) and ST(i)
FUCOM compare ST(0) and ST(1)
FUCOMP compare ST(0) and ST(1); pop one element from stack.
FUCOMP compare ST(0) and ST(1); pop two elements from stack.
The instructions perform just like FCOM, but an exception is raised only if one of the operands is SNaN, while QNaN numbers are processed smoothly.
FXCH ST(i) exchange values in ST(0) and ST(i)
FXCH exchange values in ST(0) and ST(1)
**Instructions having printable ASCII opcode**

(In 32-bit mode).

These can be suitable for shellcode construction. See also: 8.11.1 on page 884.

.1.7 npad

It is an assembly language macro for aligning labels on a specific boundary.

That's often needed for the busy labels to where the control flow is often passed, e.g., loop body starts. So the CPU can load the data or code from the memory effectively, through the memory bus, cache lines, etc.

Taken from listing.inc (MSVC):

By the way, it is a curious example of the different NOP variations. All these instructions have no effects whatsoever, but have a different size.

Having a single idle instruction instead of couple of NOP-s, is accepted to be better for CPU performance.

.2 ARM

.2.1 Terminology

ARM was initially developed as 32-bit CPU, so that’s why a word here, unlike x86, is 32-bit.

byte 8-bit. The DB assembly directive is used for defining variables and arrays of bytes.

halfword 16-bit. DCW assembly directive —“—.

word 32-bit. DCD assembly directive —“—.

doubleword 64-bit.

(For statistics collecting purposes) if you’ve read this far, please click here. Thanks!
.2.2 Versions

- ARMv4: Thumb mode introduced.
- ARMv6: used in iPhone 1st gen., iPhone 3G (Samsung 32-bit RISC ARM 1176JZ(F)-S that supports Thumb-2)
- ARMv7: Thumb-2 was added (2003). was used in iPhone 3GS, iPhone 4, iPad 1st gen. (ARM Cortex-A8), iPad 2 (Cortex-A9), iPad 3rd gen.
- ARMv7s: New instructions added. iPhone 5, iPhone 5c, iPad 4th gen. (Apple A6).
- ARMv8: 64-bit CPU, AKA ARM64 AKA AArch64. Was used in iPhone 5S, iPad Air (Apple A7). There is no Thumb mode in 64-bit mode, only ARM (4-byte instructions).

.2.3 32-bit ARM (AArch32)

General purpose registers

- R0 — function result is usually returned using R0
- R1...R12 — GPRs
- R13 — AKA SP (stack pointer)
- R14 — AKA LR (link register)
- R15 — AKA PC (program counter)

R0-R3 are also called “scratch registers”: the function’s arguments are usually passed in them, and the values in them are not required to be restored upon the function’s exit.

Current Program Status Register (CPSR)

S-registers are 32-bit, used for the storage of single precision numbers.

D-registers are 64-bit ones, used for the storage of double precision numbers.

D- and S-registers share the same physical space in the CPU—it is possible to access a D-register via the S-registers (it is senseless though).

Likewise, the NEON Q-registers are 128-bit ones and share the same physical space in the CPU with the other floating point registers.

In VFP 32 S-registers are present: S0..S31.

In VFPv2 there 16 D-registers are added, which in fact occupy the same space as S0..S31.

In VFPv3 (NEON or “Advanced SIMD”) there are 16 more D-registers, D0..D31, but the D16..D31 registers are not sharing space with any other S-registers.

In NEON or “Advanced SIMD” another 16 128-bit Q-registers were added, which share the same space as D0..D31.

### 64-bit ARM (AArch64)

#### General purpose registers

The number of registers was doubled since AArch32.

- **X0** — function result is usually returned using X0
- **X0...X7** — Function arguments are passed here.
- **X8**
- **X9..X15** — are temporary registers, the callee function can use and not restore them.
- **X16**
- **X17**
- **X18**
- **X19...X29** — callee function can use them, but must restore them upon exit.
- **X29** — used as FP (at least GCC)
- **X30** — “Procedure Link Register” AKA LR (link register).
- **X31**—register always contains zero AKA XZR or “Zero Register”. It’s 32-bit part is called WZR.
- **SP**, not a general purpose register anymore.

See also: [Procedure Call Standard for the ARM 64-bit Architecture (AArch64), (2013)](http://www.arm.com)

The 32-bit part of each X-register is also accessible via W-registers (W0, W1, etc.).

<table>
<thead>
<tr>
<th>High 32-bit part</th>
<th>low 32-bit part</th>
</tr>
</thead>
<tbody>
<tr>
<td>X0</td>
<td>W0</td>
</tr>
</tbody>
</table>

#### Instructions

There is a -S suffix for some instructions in ARM, indicating that the instruction sets the flags according to the result. Instructions which lacks this suffix are not modify flags. For example ADD unlike ADDS will add two numbers, but the flags will not be touched. Such instructions are convenient to use between CMP where the flags are set and, e.g. conditional jumps, where the flags are used. They are also better in terms of data dependency analysis (because less number of registers are modified during execution).

</tbody>
</table>

### .3 MIPS

#### .3.1 Registers

(O32 calling convention)

**General purpose registers GPR**

<table>
<thead>
<tr>
<th>Number</th>
<th>Pseudoname</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0</td>
<td>$ZERO</td>
<td>Always zero. Writing to this register is like NOP.</td>
</tr>
<tr>
<td>$1</td>
<td>$AT</td>
<td>Used as a temporary register for assembly macros and pseudo instructions.</td>
</tr>
<tr>
<td>$2 ... $3</td>
<td>$V0 ... $V1</td>
<td>Function result is returned here.</td>
</tr>
<tr>
<td>$4 ... $7</td>
<td>$A0 ... $A3</td>
<td>Function arguments.</td>
</tr>
<tr>
<td>$8 ... $15</td>
<td>$T0 ... $T7</td>
<td>Used for temporary data.</td>
</tr>
<tr>
<td>$16 ... $23</td>
<td>$S0 ... $S7</td>
<td>Used for temporary data*.</td>
</tr>
<tr>
<td>$24 ... $25</td>
<td>$T8 ... $T9</td>
<td>Used for temporary data.</td>
</tr>
<tr>
<td>$26 ... $27</td>
<td>$K0 ... $K1</td>
<td>Reserved for OS kernel.</td>
</tr>
<tr>
<td>$28</td>
<td>$GP</td>
<td>Global Pointer**.</td>
</tr>
<tr>
<td>$29</td>
<td>$SP</td>
<td>SP*.</td>
</tr>
<tr>
<td>$30</td>
<td>$FP</td>
<td>FP*.</td>
</tr>
<tr>
<td>$31</td>
<td>$RA</td>
<td>RA.</td>
</tr>
<tr>
<td>n/a</td>
<td>PC</td>
<td>PC.</td>
</tr>
<tr>
<td>n/a</td>
<td>HI</td>
<td>high 32 bit of multiplication or division remainder***.</td>
</tr>
<tr>
<td>n/a</td>
<td>LO</td>
<td>low 32 bit of multiplication and division remainder***.</td>
</tr>
</tbody>
</table>

**Floating-point registers**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$F0..F1</td>
<td>Function result returned here.</td>
</tr>
<tr>
<td>$F2..F3</td>
<td>Not used.</td>
</tr>
<tr>
<td>$F4..F11</td>
<td>Used for temporary data.</td>
</tr>
<tr>
<td>$F12..F15</td>
<td>First two function arguments.</td>
</tr>
<tr>
<td>$F16..F19</td>
<td>Used for temporary data.</td>
</tr>
<tr>
<td>$F20..F31</td>
<td>Used for temporary data*.</td>
</tr>
</tbody>
</table>

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
3.2 Instructions

There are 3 kinds of instructions:

- **R-type**: those which have 3 registers. R-instruction usually have the following form:

  \[
  \text{instruction destination, source1, source2}
  \]

  One important thing to keep in mind is that when the first and second register are the same, IDA may show the instruction in its shorter form:

  \[
  \text{instruction destination/source1, source2}
  \]

  That somewhat reminds us of the Intel syntax for x86 assembly language.

- **I-type**: those which have 2 registers and a 16-bit immediate value.

- **J-type**: jump/branch instructions, have 26 bits for encoding the offset.

### Jump instructions

What is the difference between B- instructions (BEQ, B, etc.) and J- ones (JAL, JALR, etc.)?

The B-instructions have an I-type, hence, the B-instructions’ offset is encoded as a 16-bit immediate. JR and JALR are R-type and jump to an absolute address specified in a register. J and JAL are J-type, hence the offset is encoded as a 26-bit immediate.

In short, B-instructions can encode a condition (B is in fact pseudo instruction for \text{BEQ $ZERO, $ZERO, \text{LABEL}}\), while J-instructions can’t.

4 Some GCC library functions

<table>
<thead>
<tr>
<th>name</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>__divdi3</td>
<td>signed division</td>
</tr>
<tr>
<td>__moddi3</td>
<td>getting remainder (modulo) of signed division</td>
</tr>
<tr>
<td>__udivdi3</td>
<td>unsigned division</td>
</tr>
<tr>
<td>__umoddi3</td>
<td>getting remainder (modulo) of unsigned division</td>
</tr>
</tbody>
</table>

5 Some MSVC library functions

\ll in function name stands for “long long”, e.g., a 64-bit data type.

<table>
<thead>
<tr>
<th>name</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>__alldiv</td>
<td>signed division</td>
</tr>
<tr>
<td>__allmul</td>
<td>multiplication</td>
</tr>
<tr>
<td>__allrem</td>
<td>remainder of signed division</td>
</tr>
<tr>
<td>__allshr</td>
<td>shift left</td>
</tr>
<tr>
<td>__aulldiv</td>
<td>unsigned division</td>
</tr>
<tr>
<td>__aultrem</td>
<td>remainder of unsigned division</td>
</tr>
<tr>
<td>__aultshr</td>
<td>unsigned shift right</td>
</tr>
</tbody>
</table>

Multiplication and shift left procedures are the same for both signed and unsigned numbers, hence there is only one function for each operation here.

The source code of these function can be found in the installed MSVS, in VC\text{crt/src/intel/*}.asm.

.6 Cheatsheets

.6.1 IDA

Hot-keys cheatsheet:

<table>
<thead>
<tr>
<th>key</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Space</td>
<td>switch listing and graph view</td>
</tr>
<tr>
<td>C</td>
<td>convert to code</td>
</tr>
<tr>
<td>D</td>
<td>convert to data</td>
</tr>
<tr>
<td>A</td>
<td>convert to string</td>
</tr>
<tr>
<td>*</td>
<td>convert to array</td>
</tr>
<tr>
<td>U</td>
<td>undefined</td>
</tr>
<tr>
<td>O</td>
<td>make offset of operand</td>
</tr>
<tr>
<td>H</td>
<td>make decimal number</td>
</tr>
<tr>
<td>R</td>
<td>make char</td>
</tr>
<tr>
<td>B</td>
<td>make binary number</td>
</tr>
<tr>
<td>Q</td>
<td>make hexadecimal number</td>
</tr>
<tr>
<td>N</td>
<td>rename identifier</td>
</tr>
<tr>
<td>?</td>
<td>calculator</td>
</tr>
<tr>
<td>G</td>
<td>jump to address</td>
</tr>
<tr>
<td>:</td>
<td>add comment</td>
</tr>
<tr>
<td>Ctrl-X</td>
<td>show references to the current function, label, variable</td>
</tr>
<tr>
<td></td>
<td>(incl. in local stack)</td>
</tr>
<tr>
<td>X</td>
<td>show references to the function, label, variable, etc.</td>
</tr>
<tr>
<td>Alt-I</td>
<td>search for constant</td>
</tr>
<tr>
<td>Ctrl-I</td>
<td>search for the next occurrence of constant</td>
</tr>
<tr>
<td>Alt-B</td>
<td>search for byte sequence</td>
</tr>
<tr>
<td>Ctrl-B</td>
<td>search for the next occurrence of byte sequence</td>
</tr>
<tr>
<td>Alt-T</td>
<td>search for text (including instructions, etc.)</td>
</tr>
<tr>
<td>Ctrl-T</td>
<td>search for the next occurrence of text</td>
</tr>
<tr>
<td>Alt-P</td>
<td>edit current function</td>
</tr>
<tr>
<td>Enter</td>
<td>jump to function, variable, etc.</td>
</tr>
<tr>
<td>Esc</td>
<td>get back</td>
</tr>
<tr>
<td>Num -</td>
<td>fold function or selected area</td>
</tr>
<tr>
<td>Num +</td>
<td>unhide function or area</td>
</tr>
</tbody>
</table>

Function/area folding may be useful for hiding function parts when you realize what they do. This is used in m yscript\(^\text{13}\) for hiding some often used patterns of inline code.

.6.2 OllyDbg

Hot-keys cheatsheet:

<table>
<thead>
<tr>
<th>hot-key</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>F7</td>
<td>trace into</td>
</tr>
<tr>
<td>F8</td>
<td>step over</td>
</tr>
<tr>
<td>F9</td>
<td>run</td>
</tr>
<tr>
<td>Ctrl-F2</td>
<td>restart</td>
</tr>
</tbody>
</table>

.6.3 MSVC

Some useful options which were used through this book.\(^\text{13}\)

\(^\text{13}\)GitHub

(For statistics collecting purposes) if you’ve read this far, please click [here](#). Thanks!
Some information about MSVC versions: **5.1.1 on page 698.**

### 6.4 GCC

Some useful options which were used through this book.

<table>
<thead>
<tr>
<th>option</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-Os</code></td>
<td>code size optimization</td>
</tr>
<tr>
<td><code>-O3</code></td>
<td>maximum optimization</td>
</tr>
<tr>
<td><code>-regparm=</code></td>
<td>how many arguments are to be passed in registers</td>
</tr>
<tr>
<td><code>-o file</code></td>
<td>set name of output file</td>
</tr>
<tr>
<td><code>-g</code></td>
<td>produce debugging information in resulting executable</td>
</tr>
<tr>
<td><code>-S</code></td>
<td>generate assembly listing file</td>
</tr>
<tr>
<td><code>-masm=intel</code></td>
<td>produce listing in Intel syntax</td>
</tr>
<tr>
<td><code>-fno-inline</code></td>
<td>do not inline functions</td>
</tr>
</tbody>
</table>

### 6.5 GDB

Some of commands we used in this book:
<table>
<thead>
<tr>
<th>option</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>break filename.c:number</td>
<td>set a breakpoint on line number in source code</td>
</tr>
<tr>

Glossary

anti-pattern Generally considered as bad practice. 32, 76, 471

arithmetic mean a sum of all values divided by their count. 526

atomic operation "ατομική" stands for “indivisible” in Greek, so an atomic operation is guaranteed not to be interrupted by other threads. 641, 788

basic block a group of instructions that do not have jump/branch instructions, and also don’t have jumps inside the block from the outside. In IDA it looks just like as a list of instructions without empty lines. 690, 977, 978

callee A function being called by another. 32, 46, 66, 86, 97, 99, 101, 424, 471, 551, 650, 733-736, 738, 739, 1016

caller A function calling another. 6, 8, 10, 29, 46, 86, 97, 98, 100, 108, 156, 157, 424, 476, 551, 733, 735, 736, 739

compiler intrinsic A function specific to a compiler which is not an usual library function. The compiler generates a specific machine code instead of a call to it. Often, it’s a pseudofunction for a specific CPU instruction. Read more: (11.3 on page 972). 1007

CP/M Control Program for Microcomputers: a very basic disk OS used before MS-DOS. 885

decrement Decrease by 1. 18, 186, 205, 445, 725, 1000, 1003, 1007

dongle Dongle is a small piece of hardware connected to LPT printer port (in past) or to USB. 815

endianness Byte order. 21, 78, 349, 1004

GiB Gibibyte: $2^{30}$ or 1024 mebibytes or 1073741824 bytes. 16

heap usually, a big chunk of memory provided by the OS so that applications can divide it by themselves as they wish. malloc()/free() work with the heap. 30, 351, 567, 569, 570, 582, 584, 599, 600, 631, 755, 756

increment Increase by 1. 16, 19, 186, 190, 205, 211, 329, 332, 445, 1000

integral data type usual numbers, but not a real ones. may be used for passing variables of boolean data type and enumerations. 233

jump offset a part of the JMP or Jcc instruction’s opcode, to be added to the address of the next instruction, and this is how the new PC is calculated. May be negative as well. 93, 133, 1000

kernel mode A restrictions-free CPU mode in which the OS kernel and drivers execute. cf. user mode. 1027

leaf function A function which does not call any other function. 27, 32

link register (RISC) A register where the return address is usually stored. This makes it possible to call leaf functions without using the stack, i.e., faster. 31, 816, 1013, 1014

loop unwinding It is when a compiler, instead of generating loop code for $n$ iterations, generates just $n$ copies of the loop body, in order to get rid of the instructions for loop maintenance. 188
**name mangling** used at least in C++, where the compiler needs to encode the name of class, method and argument types in one string, which will become the internal name of the function. You can read more about it here: 3.19.1 on page 549, 549, 699, 700

**NaN** not a number: a special cases for floating point numbers, usually signaling about errors. 235, 257, 796

**NEON** AKA “Advanced SIMD”—SIMD from ARM. 1014

**NOP** “no operation”, idle instruction. 725

**NTAPI** API available only in the Windows NT line. Largely not documented by Microsoft. 794

**padding** Padding in English language means to stuff a pillow with something to give it a desired (bigger) form. In computer science, padding means to add more bytes to a block so it will have desired size, like $2^n$ bytes.. 707

**PDB** (Win32) Debugging information file, usually just function names, but sometimes also function arguments and local variables names. 698, 758, 794, 795, 802, 803, 868

**POKE** BASIC language instruction for writing a byte at a specific address. 725

**product** Multiplication result. 98, 226, 229, 411, 436, 459

**quotient** Division result. 220, 222, 224, 225, 229, 435, 504, 527

**real number** numbers which may contain a dot. this is float and double in C/C++. 220

**register allocator** The part of the compiler that assigns CPU registers to local variables. 204, 309, 425

**reverse engineering** act of understanding how the thing works, sometimes in order to clone it. iv, 1007

**security cookie** A random value, different at each execution. You can read more about it here: 1.26.3 on page 283. 778

**stack frame** A part of the stack that contains information specific to the current function: local variables, function arguments, RA, etc.. 67, 68, 98, 484, 778

**stack pointer** A register pointing to a place in the stack. 10, 11, 19, 30, 34, 42, 54, 55, 73, 99, 551, 650, 733–736, 995, 1001, 1013, 1021

**stdout** standard output. 21, 35, 156

**tail call** It is when the compiler (or interpreter) transforms the recursion (tail recursion) into an iteration for efficiency. 488

**thunk function** Tiny function with a single role: call another function. 22, 41, 395, 816, 825

**tracer** My own simple debugging tool. You can read more about it here: 7.2.1 on page 790. 191–193, 617, 702, 713, 716, 774, 783, 870, 876, 880, 882, 971

**user mode** A restricted CPU mode in which it all application software code is executed. cf. kernel mode. 832, 1026

**Windows NT** Windows NT, 2000, XP, Vista, 7, 8, 10. 293, 422, 649, 706, 747, 757, 787, 887, 1006

**word** data type fitting in GPR. In the computers older than PCs, the memory size was often measured in words rather than bytes.. 452–455, 460, 573, 632

**xoring** often used in the English language, which implying applying the XOR operation. 778, 827, 830
